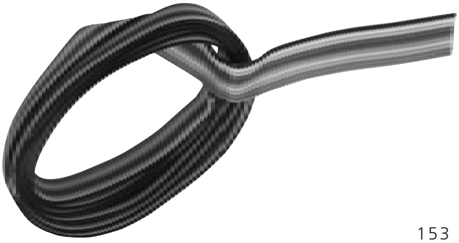
En una fuente lineal, el transformador se encarga de reducir la tensión alterna de la red de distribución a un nivel aceptable para el circuito rectificador. Además, proporciona aislación galvánica. Su funcionamiento se basa en el fenómeno de inducción electromagnética. Está compuesto por dos bobinas devanadas en un núcleo de hierro. La de entrada se denomina devanado primario, y la de salida, devanado secundario. El cociente entre los voltajes en las terminales de ambas bobinas (relación de transformación) es directamente proporcional al cociente de las vueltas de los devanados de las bobinas. Esto significa, por ejemplo, que la tensión de línea de 220 V se verá reducida a 20 V si el número de vueltas del secundario es la décima parte del número de vueltas del primario. Como la potencia se mantiene, la corriente que pasa por el primario será la décima parte de lo que circule por el secundario, según la carga. Para fuentes lineales, el transformador más frecuente es el que posee un núcleo de tipo E-I. Este se emplea en aplicaciones en las cuales bajar los costos es más importante que minimizar el flujo magnético que puede interferir en el funcionamiento del resto del circuito. Para disminuir este efecto se utilizan transformadores toroidales, en los que el núcleo tiene forma de anillo, sobre el cual se bobinan primario y secundario. El flujo magnético queda confinado en el núcleo, y las interferencias son mínimas.

El transformador reduce la tensión alterna de la red a un nivel aceptable para el circuito rectificador



www.FreeLibros.me

¿CÓMO ELEGIR?

La elección de un transformador a partir de un voltaje y una corriente de salida dados es, en principio, simple, pero en la práctica nos llevará a un proceso de prueba y error (**Figura 6**).

Si queremos calcular la tensión de salida del transformador necesaria para una tensión de fuente adecuada, debemos tener en cuenta la caída de voltaje que existe en el rectificador de potencia. Los rectificadores tienen un valor de referencia a una determinada corriente; para circuitos chicos se puede tomar 1 V como referencia por cada diodo. Hay que buscar una relación de transformación tal, que la tensión de salida del transformador se encuentre por encima de la tensión de salida de la fuente. Un valor mayor que 3 V será suficiente. Si vamos a utilizar un regulador en la salida, no es conveniente excedernos con esta diferencia de tensiones, ya que cuanto mayor sea esta, mejor será la disipación en el regulador.

Un detalle para tener en cuenta es que el fabricante nos proporciona el dato de tensión de salida del transformador en valor eficaz, por lo que debemos multiplicarlo por la raíz cuadrada de 2 (relación entre valor pico y valor eficaz), con el fin de obtener el valor pico de alterna.

EL RECTIFICADOR

Se denomina rectificador a cualquier dispositivo eléctrico que presente una resistencia pequeña a la corriente en un sentido, y una resistencia grande en el opuesto. Este dispositivo es capaz de convertir una forma de onda de entrada sinusoidal, cuyo valor medio es cero, en una forma de onda continua pulsante, con su correspondiente valor medio. Para la rectificación se utilizan uno o más diodos. Estos semiconductores permiten el paso de una corriente en un sentido y lo bloquean en el otro. Estudiaremos aquí las configuraciones de rectificación más habituales.

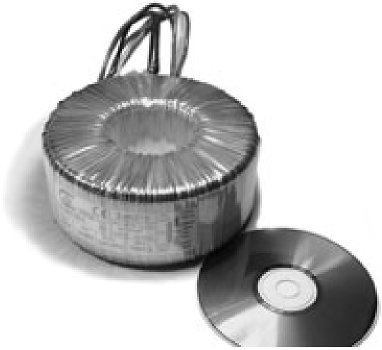


FIGURA 6.
Un transformador toroidal. En este caso, el flujo magnético queda concentrado uniformemente en el núcleo, lo que minimiza las interferencias al resto del circuito.

FUENTES SIN TRANSFORMADOR

Estas proporcionan una alternativa de bajo costo. Su funcionamiento se basa en el principio de impedancia: utilizan un capacitor para reducir el voltaje de entrada, y para proporcionar una tensión de salida continua emplean un diodo zener.

www.FreeLibros.me

EL RECTIFICADOR DE MEDIA ONDA

Esta configuración de rectificación consiste en interponer un diodo entre la fuente de tensión (el secundario del transformador) y la carga que representa el circuito por alimentar (**Figura 7**). Cuando la tensión de la fuente está en su semiciclo positivo, el sentido de la corriente es favorable y esta circula. Si consideramos que no existe caída de tensión en el diodo, la forma de onda de la tensión en la carga es igual a la del secundario durante todo el semiciclo. En cambio, si la tensión de fuente se encuentra en su semiciclo negativo, el diodo bloquea la corriente y, entonces, el voltaje en la carga es nulo.

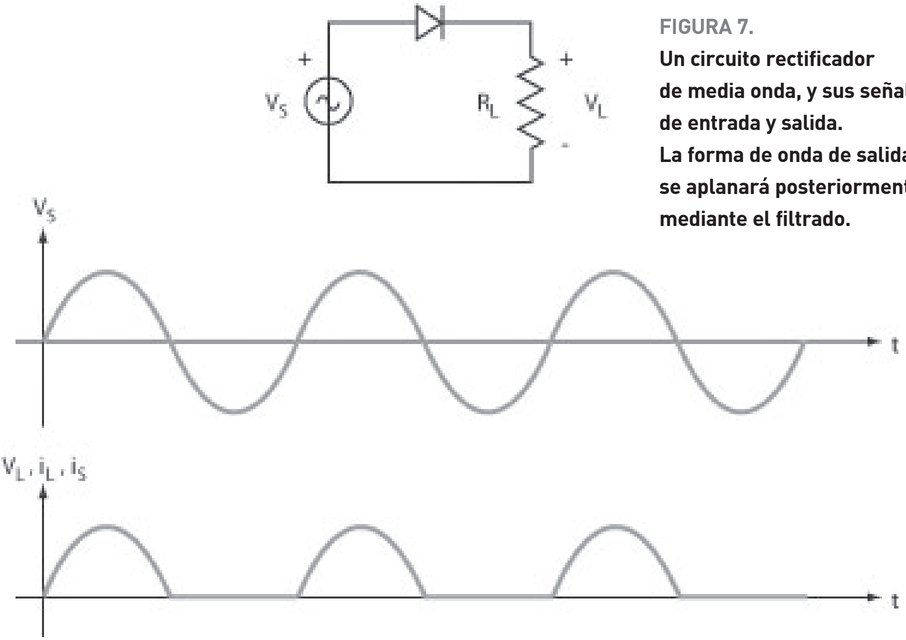

FIGURA 7.
Un circuito rectificador de media onda, y sus señales de entrada y salida. La forma de onda de salida se aplanará posteriormente mediante el filtrado.

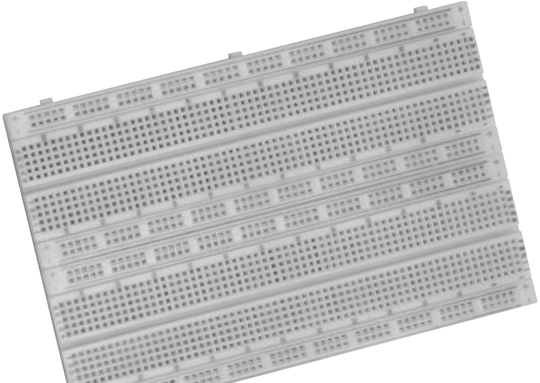
DESVENTAJAS DEL RECTIFICADOR DE MEDIA ONDA

El rectificador de media onda no permite utilizar toda la energía disponible, debido a que, en los semiciclos negativos de la tensión del secundario del transformador, el diodo bloquea la corriente y no llega energía a la carga.

www.FreeLibros.me

LOS RECTIFICADORES DE ONDA COMPLETA

Existen dos tipos de rectificadores de onda completa. El primero se logra utilizando dos fuentes en contrafase en vez de una sola, y colocando en cada una de ellas un rectificador de media onda. Se emplea un transformador con doble devanado en el secundario, tomándose el punto medio como masa común (**Figura 8**).



> El rectificador de onda completa del transformador de punto medio emplea dos fuentes en contrafase en vez de una sola

Cuando la señal de alterna de entrada está en su semiciclo positivo, el diodo **D1** conduce, y el **D2**, no. Entonces, la tensión de entrada queda aplicada directamente a la carga a través de **D1** y con una polaridad positiva. Cuando la forma de onda de entrada se encuentra en su semiciclo negativo, estará en el semiciclo positivo en el bobinado en contrafase; entonces conduce **D2**, por lo cual otra vez se aplica una tensión de fuente positiva a la carga. En este caso no existe magnetización neta permanente en el transformador y, además, se aprovecha la totalidad de la forma de onda de entrada.

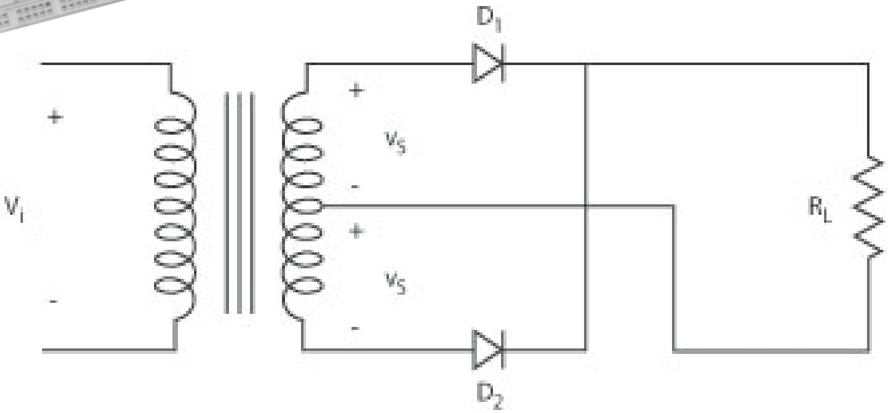


FIGURA 8. Un rectificador de onda completa con un transformador con doble devanado secundario, también llamado transformador de punto medio.

www.FreeLibros.me

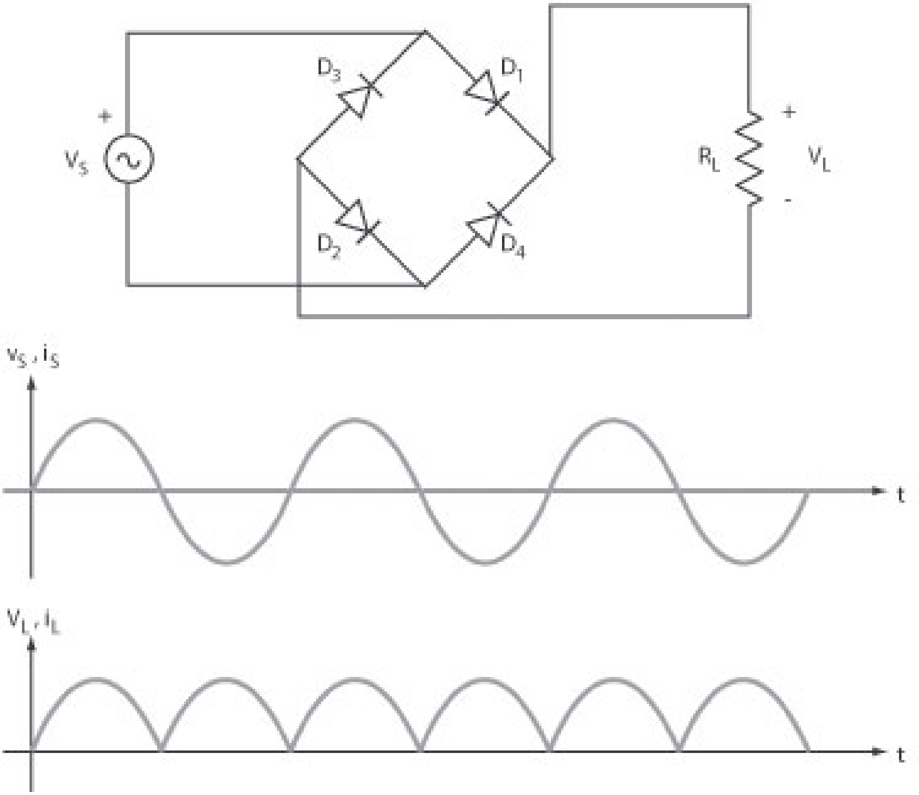

FIGURA 9. **Un circuito rectificador de onda completa tipo puente. Vemos cómo, al ser un rectificador de onda completa, se aprovecha toda la energía disponible.**

RECTIFICADOR PUENTE DE GRAETZ

Se compone de un arreglo de cuatro diodos intercalados entre la fuente de tensión y la carga (**Figura 9**). Cuando la salida del secundario es mayor que 0, los diodos **D1** y **D2** quedan polarizados en forma directa. Por lo tanto, permiten la conducción de corriente, mientras que los diodos **D3** y **D4** no conducen. Si los tomamos como elementos ideales y, por lo tanto, despreciando la caída de tensión entre sus terminales, la forma de onda de la tensión en la carga es igual a la del secundario durante todo el semiciclo. Cuando la entrada pasa a su semiciclo negativo y, por lo tanto, es ahora menor que 0, **D3** y **D4** son los que conducen, en tanto que **D1** y **D2** bloquean el paso de corriente a través de sus terminales. Como resultado, el secundario queda "conectado al revés", y la forma de onda de la tensión en la carga es la del secundario invertida, durante todo el semiciclo.

www.FreeLibros.me

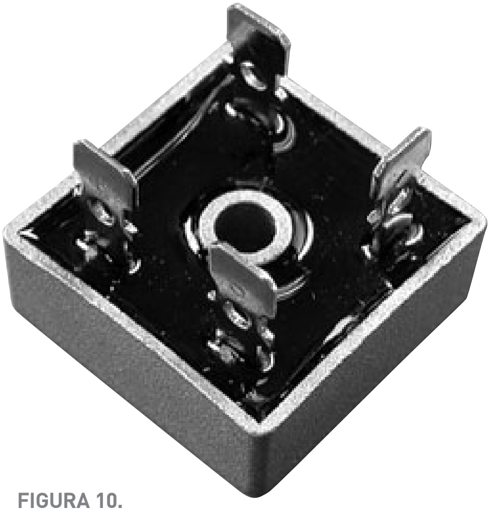

FIGURA 10.
Un puente rectificador de diodos integrado. Los cuatro diodos vienen dentro de él y así se logra una disminución en el tamaño del puente. Además, este tipo de encapsulado mejora la disipación de los diodos.

Una ventaja de los rectificadores tipo puente es que utilizan transformadores con devanado simple en el secundario, de modo que resultarán más económicos que un rectificador con transformador de doble devanado (**Figura 10**). En cuanto a las especificaciones de los diodos, estos deben ser capaces de disipar la potencia máxima necesaria y un margen de seguridad. Los diodos rectificadores se clasifican según su corriente promedio y el voltaje pico inverso. El valor medio de la corriente por el diodo es la mitad del de la carga, porque conduce sobre uno de los semiciclos solamente. La tensión inversa máxima sobre el diodo es lo que hay en el capacitor: valor de pico, más el pico inverso en el transformador; es decir, dos veces el valor de pico.

FILTROS DE SALIDA

Las formas de onda de salida de los circuitos rectificadores necesitan un filtrado para alimentar un circuito electrónico. Para este fin, se utiliza un circuito integrador que funciona como si fuera un filtro **pasabajos** para eliminar el ripple (**Figura 11**). Por lo general, este filtrado se lleva a cabo colocando un capacitor en paralelo con la carga. El funcionamiento de este sistema se basa en que el capacitor almacena energía durante el período de

El filtrado a la salida de la fuente se lleva a cabo, por lo general, colocando un capacitor en paralelo con la carga

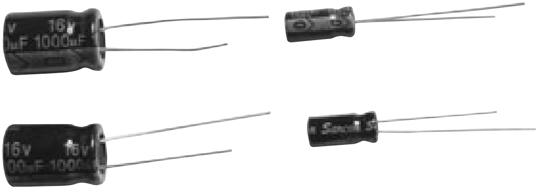
UN DATO IMPORTANTE

Para el caso del rectificador de onda completa, el funcionamiento es similar al de media onda, con la diferencia de que la caída de la tensión del capacitor debido a su descarga está con el pico negativo rectificado, donde comienza a cargarse otra vez.

www.FreeLibros.me

conducción del diodo, y la entrega a la carga en el período de no conducción. De esta manera, se prolonga el tiempo durante el cual circula corriente por la carga, y se disminuye notablemente la componente de alterna residual (ripple). Para explicar el filtrado, supongamos un rectificador de media onda con un capacitor en paralelo con la carga. Vamos a considerar que la resistencia de carga es infinita. El capacitor se cargará a la tensión máxima del secundario del transformador, y mantendrá esta tensión porque no existe ningún camino por el que pueda descargarse, ya que el diodo impide la circulación de corriente en sentido inverso. De este modo, el filtrado es perfecto.

Si suponemos que la carga es finita, el capacitor se descargará a través de ella, porque ahora cuenta con un camino para hacerlo. Cuanto mayor sea el valor de capacidad del capacitor, menor será su caída de tensión por la descarga (disminuye el ripple). Cuanto menor sea la resistencia de carga, mayor será esta caída (aumenta el ripple) **Figura 12**.



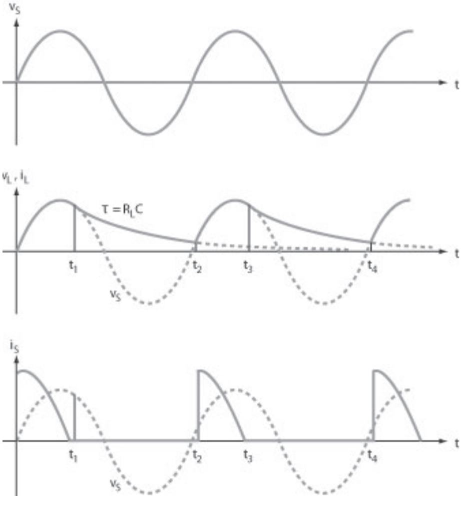


FIGURA 11.

Señal de entrada a un rectificador con filtro de capacitor, tensión, y corriente por la carga y por el diodo. La constante de descarga es ? =R x C.

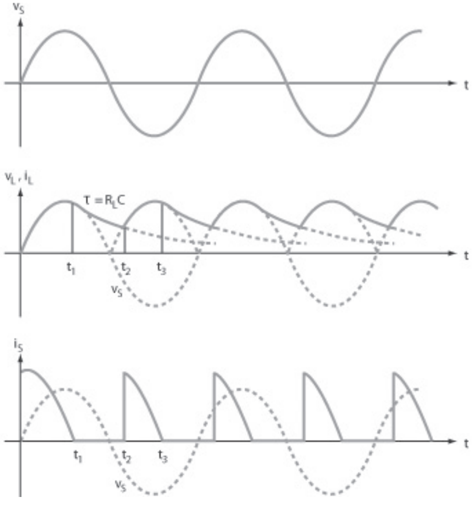

FIGURA 12.

En el diagrama podemos visualizar las formas de onda de entrada y salida de un rectificador de onda completa con filtro.

Diseño de una fuente de alimentación

En estas páginas conoceremos cuáles son las características que debemos tener en cuenta para diseñar una fuente de alimentación.

Tomemos como ejemplo un circuito que consume una corriente de **800 mA** (0,8 A) y debe ser alimentado con una tensión de **12 V**. Con estos valores, podemos calcular la potencia consumida. Recordemos que potencia **W (Watt) = I (Ampere) x E (Volt)**. Por lo tanto, el consumo será de **0,8 A x 12 V = 9,6 W**.

Nuestro transformador deberá suministrar una potencia mayor; por razones de confiabilidad, recomendamos que sea del doble.

Para pequeñas potencias, también podemos seleccionar el transformador especificando la corriente. En nuestro caso, uno de **2 A** sería más que suficiente; **2 A x 12 V = 24 W**.

Con respecto a la tensión, si bien necesitamos **12 V**, debemos dejar cierto margen para que el circuito regulador pueda operar. La tensión rectificada será el valor de pico de la tensión alterna; es decir, el producto de su valor eficaz (**12 V**) por la raíz cuadrada de **2**, casi **17 V**. A esta cifra debemos restarle la caída de tensión en los rectificadores.

Si utilizamos un rectificador en puente de onda completa (cuatro diodos), en cada ciclo de la tensión alterna estarán involucrados dos diodos. La caída de tensión por diodo será cercana a **1,2 V**. Tenemos, entonces: **17 V - 2,4 V = 14,6 V**. Esta será la tensión resultante cuando la fuente consuma cierta cantidad de corriente. Dado que debemos regular este valor a **12 V**, utilizaremos un regulador fijo de tipo **7812**.

Según las características del regulador, se necesita una tensión de entrada mínima de **14,6 V**, que asegure una regulación de la tensión de salida. Debemos dejar un poco de margen y aumentar la tensión de salida del transformador; uno de **14 V** y **20 W** será adecuado.

Los rectificadores deberán soportar la corriente media. Como utilizamos un rectificador en puente, cada diodo conduce la mitad del tiempo, y la corriente media es la mitad de la que pide la carga (**0,4 A**). Entonces, para el rectificador en puente vamos a elegir cuatro diodos de **1 A** como mínimo. El **1N4002** es perfecto para nuestros propósitos, ya que maneja **1 A** y una tensión de pico inversa de **100 V**.

UN DATO IMPORTANTE

Sobredimensionar un transformador nunca está de más. Siempre debemos considerar la peor de las situaciones, que es el trabajo continuo y al máximo de su potencia. Conviene duplicar la corriente necesaria para dejar un margen de seguridad.

www.FreeLibros.me

Mod_Cap6_xxx_xxx.qxp 04/07/2011 16:41 Página 163

TENSIÓN DE RIZADO O RIPPLE

A la salida del rectificador disponemos de una tensión positiva pulsante, no apta para aplicar a ningún circuito electrónico. El capacitor de filtro se cargará con los picos o pulsos de la tensión de salida del rectificador, y mantendrá esa tensión durante la ausencia de estos. De este modo, obtenemos una tensión continua pura, que es la que finalmente aplicaremos al regulador de tensión (**Figura 13**).

> Por cada ampere de consumo se requieren aproximadamente 2000 μF para el capacitor de filtro

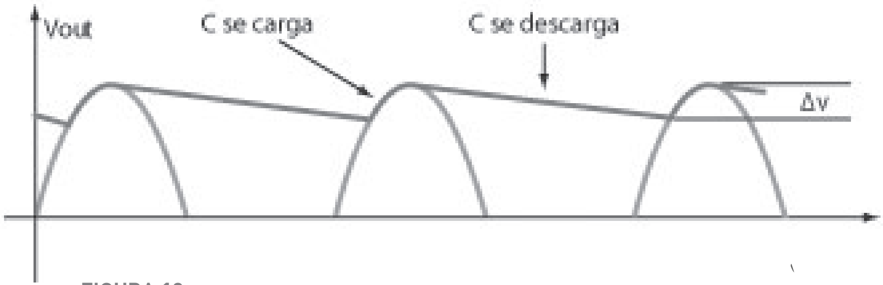

FIGURA 13.
Vout es el voltaje en el capacitor. Este se carga en el flanco creciente del ciclo hasta llegar al pico; a partir de allí, se descarga en el circuito. Circuito rectificador de media onda.

Ahora bien, debido a que un capacitor mantiene su carga durante un tiempo determinado, su capacidad debe ser lo suficientemente alta para que la tensión no decaiga entre los picos de la tensión pulsante de la salida del rectificador. Esto es lo que se conoce como rizado o ripple, y es la caída de tensión (**ΔV**) entre los "valles" de los picos de la tensión pulsante (**Figura 14**). Si conectamos un osciloscopio a una tensión con ripple, veremos una línea con pequeñas deformaciones repetitivas.

www.FreeLibros.me

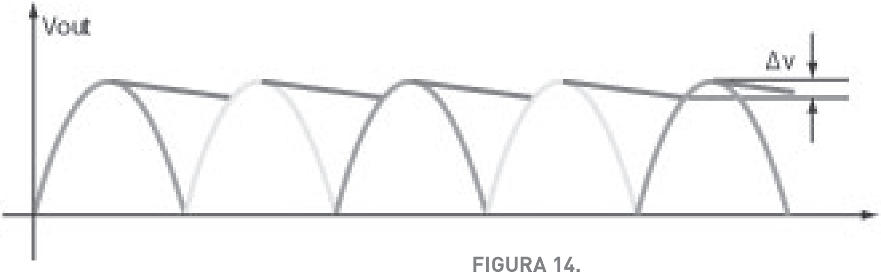

FIGURA 14.
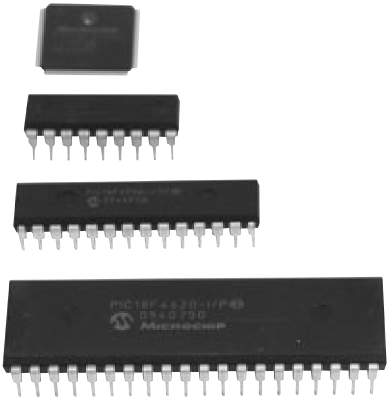
En esta imagen vemos los beneficios de la rectificación de onda completa, que, a diferencia de la de media onda, tiene menor ripple porque los ciclos están juntos entre sí y el capacitor se recarga en la mitad de tiempo.

Algunos circuitos son más inmunes que otros al rizado, pero éste sería un factor inadmisible en un amplificador de audio, ya que escucharíamos de fondo un leve zumbido producido por el ripple de la fuente.

El cálculo del capacitor se realiza estimando cuánto se puede dejar caer la tensión (**ΔV**) en el tiempo que tarda en recargarse (**Δt**), dada la corriente (**I**) que pide el circuito: **C = I x Δt / ΔV**. Una regla empírica dice que, para onda completa, por cada ampere de consumo se requieren unos **2000 μF**. La tensión que debe soportar el capacitor tiene que ser superior a la tensión rectificada; se recomienda que sea cercana al doble.
Volviendo al ejemplo anterior, un capacitor de **2200 μF** y **25 V** será suficiente, ya que consumimos casi **1 A** (**0,8 A**), pero debido a que disponemos de un transformador de 2 A, podríamos aprovechar mejor la corriente extra y colocar un capacitor de **4700 μF** y **25 V**.

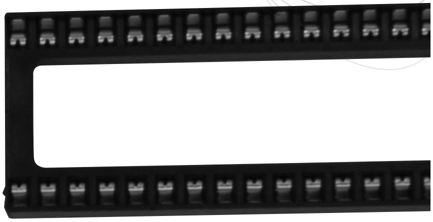


MÁS SOBRE EL RIPPLE

Con la rectificación de onda completa, en el mismo tiempo tenemos dos pulsos de la corriente rectificada en contraste con el rectificador de media onda, que sólo proporciona uno. Esto significa que, con el mismo capacitor en onda completa, habrá menor ripple.

www.FreeLibros.me

Los reguladores de voltaje



Son los dispositivos encargados de mantener un voltaje estable a lo largo del tiempo, independientemente del consumo y de los cambios de voltaje a su entrada.

En electrónica hay muchas maneras de hacer lo mismo, pero se opta siempre por la solución más segura y económica sobre la base de las necesidades del circuito.

REGULADORES FIJOS

Existen dos tipos de reguladores: en paralelo y en serie. Los primeros son utilizados cuando la demanda de corriente es baja. En ellos se emplean diodos **zener**, que tienen la propiedad de conducir cierta corriente cuando están polarizados de forma inversa y se supera determinado nivel de voltaje (**Figura 15**).

Pongamos como ejemplo un diodo zener de **5,1 V**. Si aplicamos entre ánodo y cátodo un voltaje que supere los **5,1 V**, el diodo comenzará a conducir corriente, manteniendo entre sus terminales una tensión cercana a **5,1 V**. Debido a que estos diodos tienen un límite en la conducción de corriente, se les agrega en serie con la tensión una resistencia limitadora de corriente, que se calcula considerando la corriente que requiere el circuito al cual se conecta, más la necesaria por el diodo para mantener la tensión de zener.

Existen dos tipos de reguladores: en paralelo y en serie

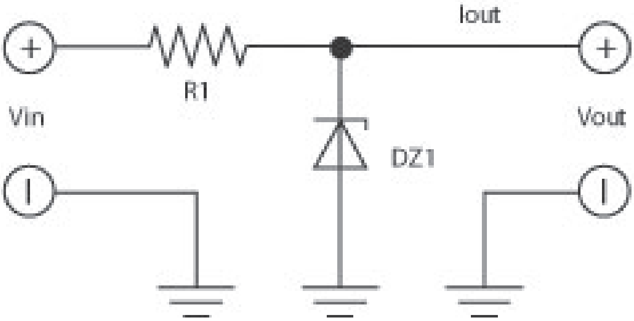


FIGURA 15.
El diodo zener deja pasar cierta corriente por sí mismo para que las variaciones de Vin (entrada) **y la corriente de carga** Iout (consumo) **no modifiquen el voltaje** Vout.

www.FreeLibros.me

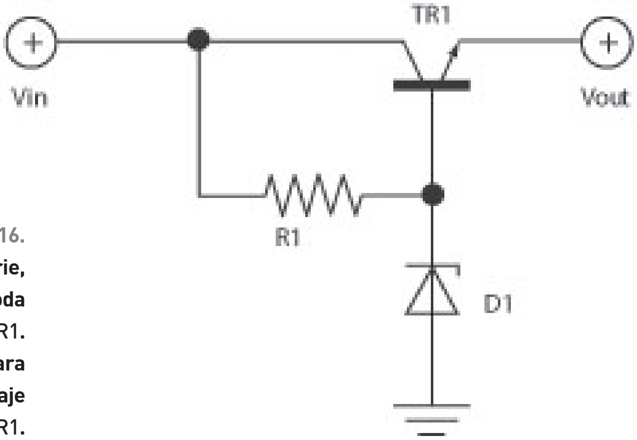

FIGURA 16.
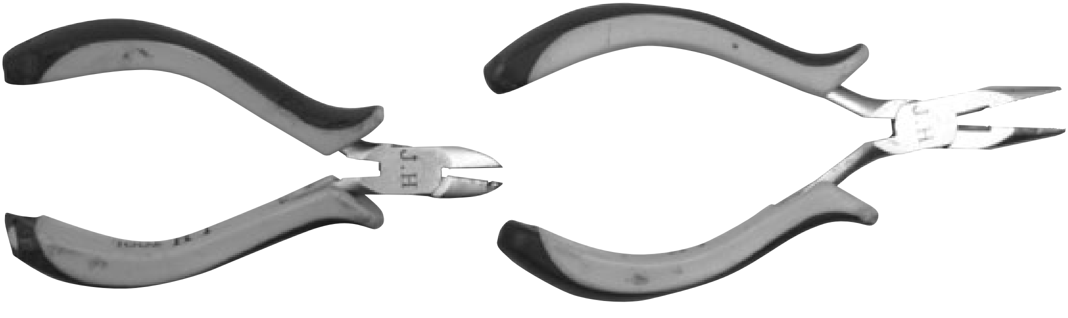
En los reguladores serie, el componente que soporta toda la corriente es el transistor TR1**. El diodo** zener **es usado para dar una referencia de voltaje a la base de** TR1**.**

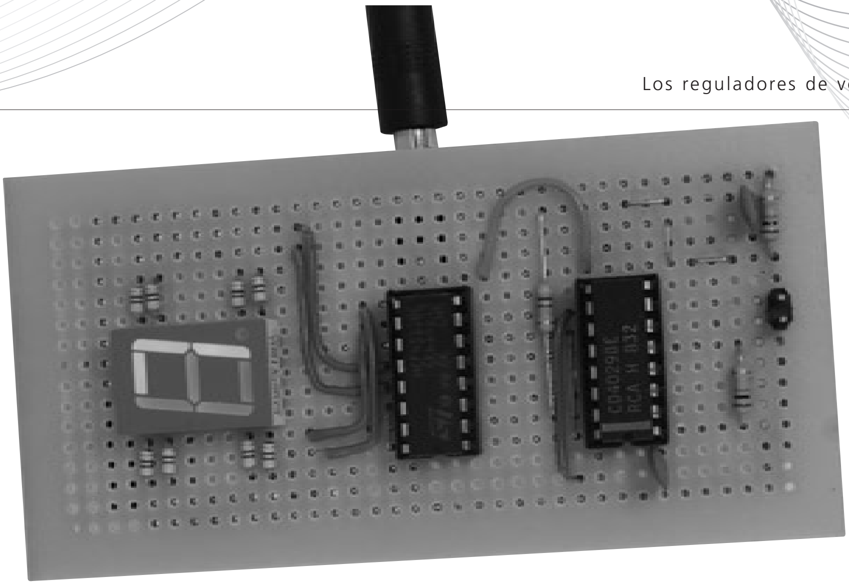
Por ejemplo, precisamos alimentar un circuito con **5,1 V** que consume una corriente de **20 mA**, y disponemos de una tensión de **14 V**. Escogemos el diodo **zener 1N4733**, que es de **5,1 V** y es capaz de disipar **1 W**. El fabricante dice que requiere, como mínimo, una corriente de **1 mA** para regular. Para asegurarnos la regulación, debemos considerar las peores condiciones, y ellas son: que la tensión de entrada disminuya (por ejemplo, que baje a **12 V**) y que el circuito consuma, por momentos, el doble de corriente (**40 mA**). A partir de estos valores calculamos la resistencia serie:

[Voltaje de entrada (el más bajo) - **voltaje del zener] / [corriente de consumo del circuito** (la máxima) **+ corriente mínima necesaria por el zener]=**

(12 V - 5,1 V) / (0,040 A + 0,001 A) = 168 Ohms



www.FreeLibros.me



Ahora supongamos que desconectamos la carga (el circuito) del diodo zener. Entonces, toda la corriente circulará por el diodo y, en el peor caso, la máxima tensión de entrada será de **(14 V - 5,1 V) / 168 Ohms = 53 mA**, correspondiente a una potencia de **5,1 V x 53 mA = 270 mW**, dentro de los parámetros de operación del diodo.

En circuitos donde se requiere mayor corriente, se apela a la regulación en serie. En este caso, se utilizan transistores conectados en serie con la tensión, y se polarizan con un elemento de referencia fija como el diodo zener.

Por último, están los reguladores integrados, como el **7805**, que en su interior tiene un circuito similar al regulador serie, pero con compensaciones por temperatura y protecciones contra cortocircuitos. Utilizan tres terminales: entrada, masa y salida.

En circuitos donde se requiere mayor corriente, se apela a la regulación en serie

Para el ejemplo anterior de la fuente de **12 V**, podremos utilizar un regulador **78T12**, que soporta hasta **3 A**. De este modo, aprovecharemos el máximo potencial del transformador.

SOBRE ZENER

Existen diodos zener de cientos de Watts. Sin embargo, su uso está restringido a ciertos circuitos de control de potencia. En nuestro caso, sólo los usaremos cuando necesitemos mantener estable un voltaje de baja corriente en determinado punto de un circuito.

www.FreeLibros.me

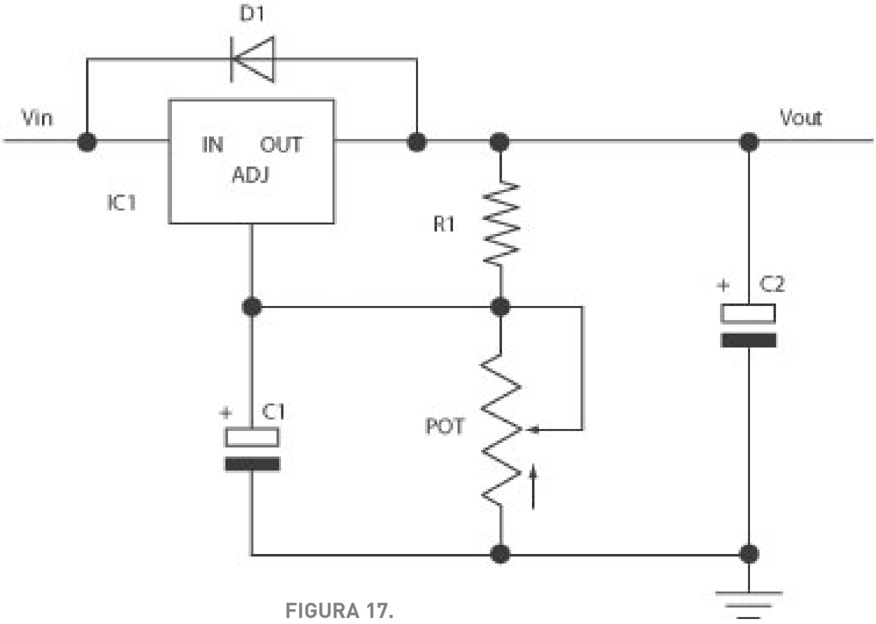


FIGURA 17.
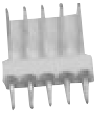
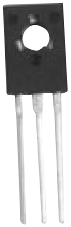
El terminal de ajuste (adj) del LM317 **se ocupa de regular su tensión de salida.**





LOS REGULADORES VARIABLES

Como su nombre lo indica, estos reguladores permiten obtener una gama continua de distintos voltajes. Gracias a ellos es posible construir una fuente de alimentación universal. Como en el caso de los reguladores fijos, los reguladores variables pueden construirse a partir de componentes discretos o por medio de circuitos integrados (**CI**) especializados. A continuación, veremos un regulador variable construido en torno al **CI LM317** (**Figura 17**).

El **CI LM317** cuenta con tres terminales: uno es utilizado como entrada de la tensión sin regular, y otro, como salida regulada. Un tercer terminal es el encargado de controlar la tensión de salida. En la hoja de datos del fabricante encontraremos los múltiples usos de este versátil regulador.

www.FreeLibros.me

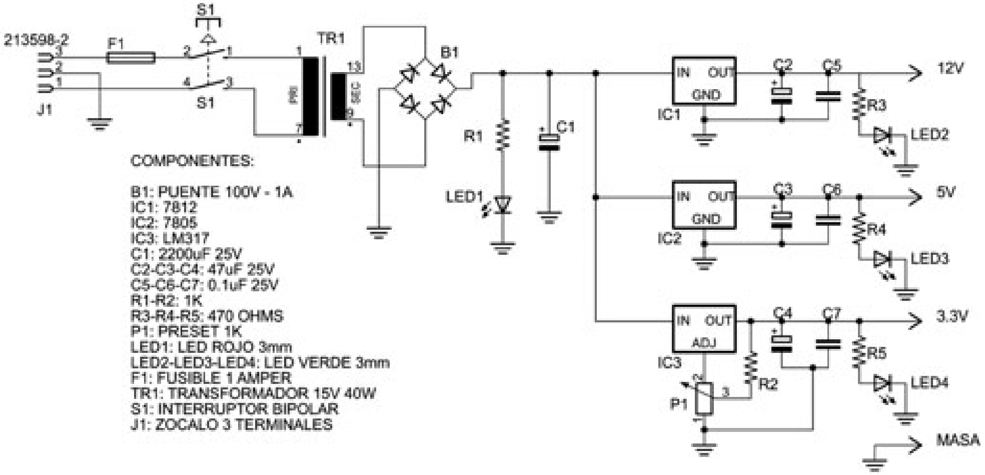
FUENTE DE ALIMENTACIÓN PARA EL TALLER

Es indispensable contar con una fuente de alimentación para realizar todas las prácticas del curso y, además, utilizarla en todos los montajes que necesitemos probar.

La siguiente fuente de alimentación está diseñada para que sea un elemento de gran valor para el técnico. Fue concebida teniendo en cuenta los múltiples voltajes que se utilizan habitualmente en electrónica digital. No desaprovecharemos la oportunidad de construir una fuente que sirva para la mayoría de los circuitos digitales. Las tensiones de salida son **3.3 V**, **5 V**, **12 V** y una corriente de **1 A**.

Como en cada uno de los proyectos, lo primero que debemos tener en claro es el esquemático que especifica detalladamente las características y componentes de la fuente de alimentación que vamos a desarrollar (**Paso a paso 1**). Tomando como ruta este esquemático, evitaremos cometer errores (**Figura 18**).

En primer lugar debemos contar con todos los elementos necesarios para armar la fuente de alimentación. En nuestro caso aplicaremos los reguladores estudiados. Para los **12 V** y **5 V** emplearemos reguladores fijos **7812** y **7805** respectivamente. Para los **3,3 V** utilizaremos el versátil regulador variable **LM317** y ajustaremos el **preset** (potenciómetro de ajuste) para **3,3 V** de salida.



COMPONENTES:

B1: PUENTE 100V - 1A
IC1: 7812
IC2: 7805
IC3: LM317
C1: 2200uF 25V
C2-C3-C4: 47uF 25V
C5-C6-C7: 0.1uF 25V
R1-R2: 1K
R3-R4-R5: 470 OHMS
P1: PRESET 1K
LED1: LED ROJO 3mm
LED2-LED3-LED4: LED VERDE 3mm
F1: FUSIBLE 1 AMPER
TR1: TRANSFORMADOR 15V 40W
S1: INTERRUPTOR BIPOLAR
J1: ZOCALO 3 TERMINALES

FIGURA 18.

El costo de realizar una fuente de un voltaje múltiple es casi el mismo que el de una fuente de voltaje único.

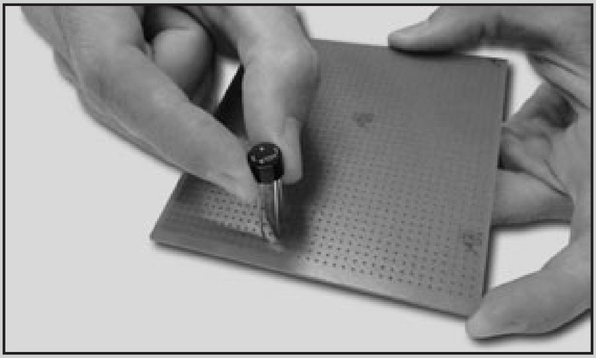
www.FreeLibros.me

PASO A PASO /1
Fuente de alimentación para el taller

1

El primer paso es definir el transformador necesario. Para este fin, basta con saber cuál será el voltaje máximo que pretende extraer de la fuente. En este caso, será de **12 V** y, según lo visto en párrafos anteriores, el transformador debe proveer **14** o **15 V** de salida. Como hay varias salidas, use uno de **40 W** aproximadamente.

2

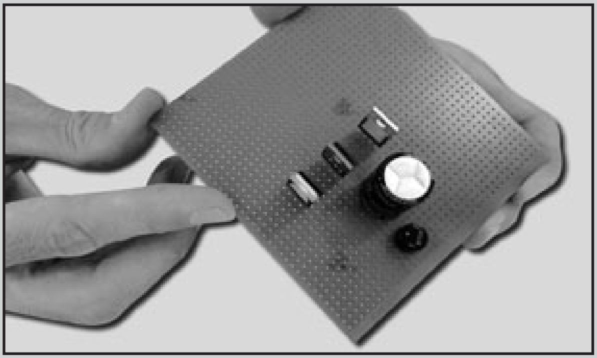


Comience por colocar el puente rectificador en la tarjeta de circuito impreso universal. Recuerde la polaridad indicada en la superficie del encapsulado, entendiendo que los símbolos ~ son las entradas de corriente alterna; **+** y **-** indican positivo y negativo respectivamente.

www.FreeLibros.me

PASO A PASO /1 (cont.)

3



Ahora coloque el capacitor principal de filtro con el terminal positivo orientado hacia el mismo terminal de salida del puente rectificador. Inserte los reguladores fijos **7812** y **7805**, como indica la imagen. De esta manera, las conexiones que deberá efectuar serán las más cortas. Introduzca el **LM317** en el PCB según la fotografía.

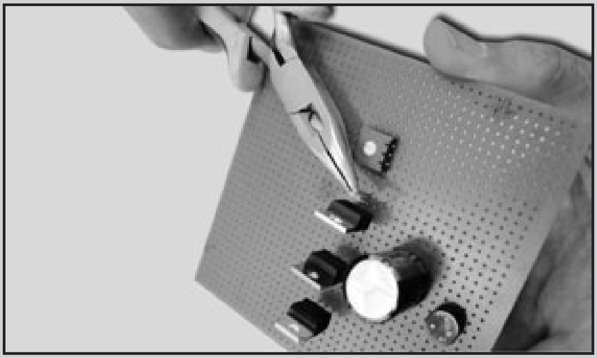
4

Es momento de girar el PCB y comenzar con la soldadura de los componentes. Suelde uno a uno los terminales hasta finalizar con todos. En este momento, puede comenzar con la conexión entre ellos y, en algunos casos, podrá emplear los mismos terminales de los componentes como conexiones, soldándolos en todo su recorrido para evitar desconexiones por vibraciones.

www.FreeLibros.me

PASO A PASO /1 (cont.)

5



Ahora introduzca el preset y la resistencia de **1K**. Gire nuevamente el PCB y suelde estos componentes. Realice las conexiones del preset y la resistencia según el esquemático. No confunda los terminales del **LM317**, ya que el primero de la izquierda es el de ajuste, el del medio es la salida, y el de la derecha, la entrada.

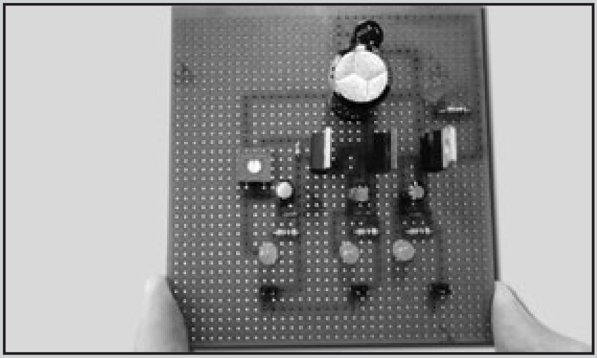
6

Coloque ahora los capacitores de desacople de salida, que consisten en uno de **10 µF 25 V** y otro de **0.1 µF**. Preste especial atención a la polaridad de estos. Por norma, los terminales más largos en los capacitores electrolíticos corresponden al terminal (+). Lo mismo ocurre con los LEDs.

www.FreeLibros.me

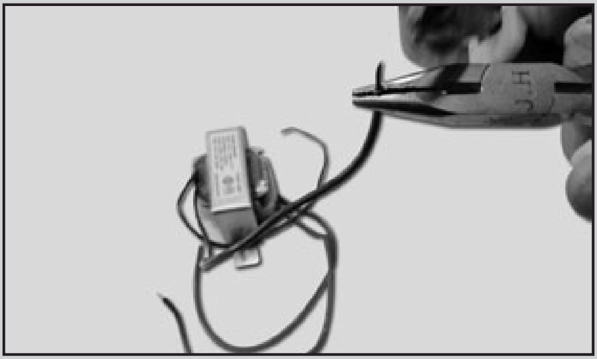
PASO A PASO /1 (cont.)

7



Ahora agregue las resistencias limitadoras de corriente para los LEDs. La de **1 K** es solo para el LED conectado a la salida del rectificador y, el resto de **470 Ohms**, para las salidas reguladas. Gire el PCB y suéldelas. Luego, agregue los LEDs dejándolos a una distancia de **1 cm** del PCB para que sean más visibles.

8

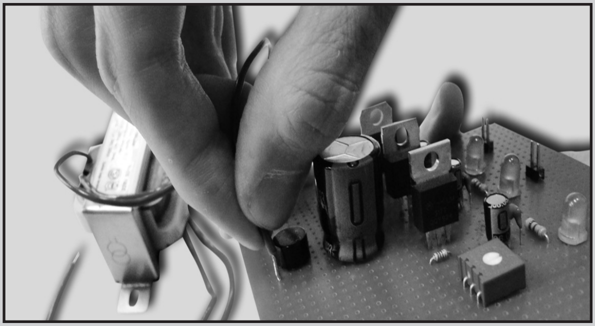


Conecte el transformadora a un interruptor y al cable para conectar a la toma de red eléctrica. Puede agregar un fusible en caso de cortocircuito. Agregue unos pines terminales al PCB para conectar las salidas de tensión a los bornes de un gabinete que escoja para la fuente. Finalice todas las conexiones según el esquemático.

www.FreeLibros.me

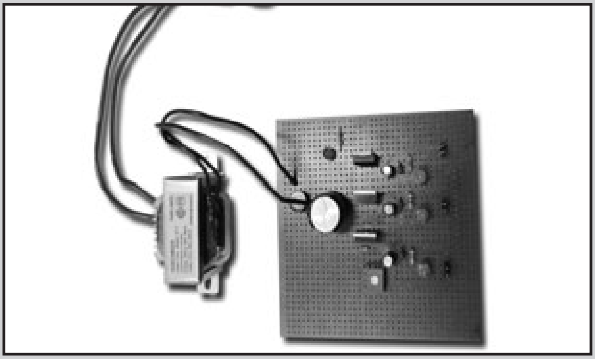
PASO A PASO /1 (cont.)

9



Conecte el secundario del transformador al PCB. Verifique con la ayuda de un multímetro configurado para medir continuidad, si no existe algún cortocircuito y si las conexiones están correctas. Preste especial atención al primario del transformador, que sea efectivamente el primario de este y no el secundario. Tome todos los recaudos antes de que su ansiedad lo lleve a conectar precipitadamente la fuente.

10



Ahora tiene la fuente armada, los componentes montados al PCB y el transformador con sus cables rojos listos para enchufar a la red eléctrica. Luego, solo tiene que encender el interruptor. Si nota algo fuera de lo común, como humo o un ruido anormal, desconecte inmediatamente todo y revise con detenimiento todo el circuito. Si todo funciona bien, deberá ver iluminarse los LEDs.

www.FreeLibros.me

PASO A PASO /1 (cont.)

11

Conecte el multímetro a la salida de **3,3 V** para medir voltaje y, con un destornillador, ajuste el preset para obtener exactamente **3,3 V** en la pantalla del multímetro. Verifique que las salidas de **5** y **12 V** indiquen esos voltajes o aproximados **+/-0,1 V**.

En este último capítulo, estudiamos las características principales de las fuentes lineales y conmutadas conectadas a la red domiciliaria. Además analizamos los bloques constitutivos de una fuente de alimentación y sus características fundamentales.
Realizamos el diseño de una fuente de alimentación simple, partiendo de las características de operación de un circuito electrónico. Vimos el armado de una fuente de taller que nos proveerá de las tensiones más comunes para trabajar con proyectos de Electrónica Digital.

Apéndice

El mercado laboral

En este apéndice,
veremos las principales salidas laborales
que nos brinda la Electrónica Digital.

www.FreeLibros.me

El mercado **laboral**

La electrónica brinda en la actualidad un abanico de posibilidades laborales muy diverso. El alcance del mercado laboral hoy en día es inabarcable, ya que siempre existirá la industria que necesite digitalizar sus máquinas, desarrollar nuevas creaciones electrónicas o adaptar distintas tecnologías entre sí. Cada día es más frecuente encontrarnos en la industria o en el hogar con máquinas y dispositivos conectados a Internet. En el sector agropecuario se han realizado importantes adelantos, añadiendo unidades de control electrónico para optimizar el desempeño de las máquinas de siembra y cosecha. Muchas de estas innovaciones han sido creadas por hobbistas o técnicos electrónicos. Si bien el mercado actual y la masificación de los dispositivos electrónicos redujeron considerablemente sus costos y, en muchos casos, los hicieron descartables, existirán siempre aplicaciones que justifiquen la intervención de un técnico electrónico. Estas aplicaciones se cuentan por miles y son las que, a modo de resumen, expondremos en detalle a continuación.

La electrónica brinda en la actualidad un abanico de posibilidades laborales muy diverso

- **Ecología**: incluimos este sector ya que, con el correr de los años, será excluyente el reemplazo de antiguos sistemas eléctricos/electrónicos por sus semejantes actuales de menor consumo. En este sentido, podremos incursionar en el desarrollo de sistemas de reemplazo con los componentes actuales del mercado.

LA ELECTRÓNICA EN LA PRÁCTICA

Se efectúan diferentes tareas en la práctica diaria de la electrónica. Estas son: diagnosticar el funcionamiento de circuitos integrados, reparación y reemplazo de los pequeños componentes que forman parte de los circuitos estudiados en este libro.

www.FreeLibros.me

- **Sector industrial**: toda industria en el mundo repara y renueva anualmente sus máquinas y equipos. Estos incluyen sistemas electrónicos de medición, sensores y actuadores.
- **Sector Informático**: dispositivos de hardware de PC, sistemas UPS (*Uninterruptible Power Supply* - **Sistema Ininterrumpido de Energía**), estabilizadores de tensión, control remoto Bluetooth, placas de capturas analógicas-digitales, entre otras opciones. Todos ellos son susceptibles de ser reparados o modificados mediante la Electrónica.
- **Telemetría y Posicionamiento**: el control a distancia realizó grandes avances en las últimas décadas. Desde controles térmicos, de suelo, posicionamiento por medio de GPS (*Global Positioning System* - **Sistema de Posicionamiento Global**) o de riego remoto y mediciones de alturas en ríos. Todos estos equipos podrán ser reparados e incluso construidos y desarrollados desde cero.
- **Electromedicina**: se construyen y reparan permanentemente sistemas de baja complejidad, como incubadoras, esterilizadores y nebulizadores.
- **Seguridad**: en el campo de la seguridad, el técnico puede volcarse al diagnóstico y la reparación de alarmas, enlaces con el propietario, enlaces policiales y monitoreo.

Lo detallado hasta el momento es solo una muestra de las posibilidades laborales y de creaciones electrónicas posibles. Algunas áreas requerirán hacer un estudio particular, pero los principios electrónicos serán siempre los mismos. Por ejemplo,

Integrar significa, en términos electrónicos, vincular o unir dos o más dispositivos electrónicos entre sí

SECTOR AUTOMOTRIZ

Además de todos los sectores que detallamos, no debemos olvidarnos de la industria automotriz, en donde los sistemas electrónicos tomaron gran relevancia debido a las múltiples modificaciones que se realizaron en términos de controles de manejo, confort y motorización.

www.FreeLibros.me

Apendice_Electronica.qxp 04/07/2011 16:42 PÆgina 180

una compuerta siempre será una compuerta, pero dependiendo del uso que le demos, será la acción que realice en cada caso.

INTEGRACIÓN

Integrar significa, en términos electrónicos, vincular o unir dos o más dispositivos electrónicos entre sí, pero que cumplen funciones perfectamente definidas por separado. Hoy en día, existen miles de circuitos electrónicos con aplicaciones específicas a precios muy económicos. En muchas ocasiones, será conveniente integrar estos circuitos a nuestras necesidades en lugar de desarrollarlos y fabricarlos desde cero, ya que seguramente el costo y el tiempo resultante serán inaceptables.

Como ejemplo, supongamos que disponemos de un sistema de control de temperatura en un horno, que activa una **alarma visual** (luz) cada vez que se supera una determinada temperatura. Nosotros deseamos agregarle otro sistema para que, además, envíe un mensaje de texto **SMS** a un teléfono móvil cuando esta condición ocurra. Para ello, deberemos integrar, al sistema del horno, nuestro dispositivo SMS que permita la conexión a Internet y pueda enviar el mensaje a través de la prestadora de telefonía móvil, que dependerá de cada país en particular.

CLAVES PARA COMPRAR
UN LIBRO DE COMPUTACIÓN

1 SOBRE EL AUTOR Y LA EDITORIAL

Revise que haya un cuadro "sobre el autor", en el que se informe sobre su experiencia en el tema. En cuanto a la editorial, es conveniente que sea especializada en computación.

2 PRESTE ATENCIÓN AL DISEÑO

Compruebe que el libro tenga guías visuales, explicaciones paso a paso, recuadros con información adicional y gran cantidad de pantallas. Su lectura será más ágil y atractiva que la de un libro de puro texto.

3 COMPARE PRECIOS

Suele haber grandes diferencias de precio entre libros del mismo tema; si no tiene el valor en tapa, pregunte y compare.

4 ¿TIENE VALORES AGREGADOS?

Desde un sitio exclusivo en la Red, un Servicio de Atención al Lector, la posibilidad de leer el sumario en la Web para evaluar con tranquilidad la compra, y hasta la presencia de adecuados índices temáticos, todo suma al valor de un buen libro.

5 VERIFIQUE EL IDIOMA

No solo el del texto; también revise que las pantallas incluidas en el libro estén en el mismo idioma del programa que usted utiliza.

ELECTRÓNICA PRÁCTICA

En este libro recorreremos los conceptos básicos de la electrónica y sus aspectos prácticos. Entraremos en el taller y veremos en detalle las herramientas y los instrumentos imprescindibles. Además, conoceremos en profundidad el análisis, la construcción y la simulación de circuitos en la PC.

DENTRO DEL LIBRO ENCONTRARÁ

El taller electrónico ■ Las herramientas ■ Circuitos electrónicos ■ Protoboard ■ Construcción de circuitos impresos ■ Técnicas de soldado ■ Instrumentos de medición ■ Uso del multímetro digital ■ El osciloscopio ■ Diseño de circuitos impresos ■ Diseño y simulación ■ Simulación del cargador de baterías ■ Diseño de una fuente de alimentación ■ Los reguladores de voltaje

ELECTRONICS FROM SCRATCH

In this book we will learn the basics of Electronics as well as the practical aspects to bear in mind when dealing with analysis, simulation and construction of electronic circuits. Furthermore, we will be trained on how to use tools and electronic measuring instruments.

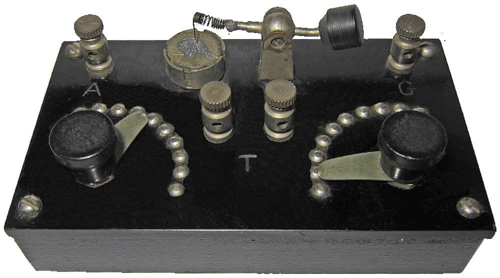
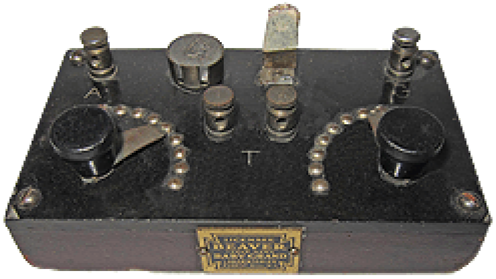
Beaver Baby Grand
Beaver Machine and Tool Company produced several variations of this crystal radio during the 1920s, and also apparently supplied the radio to India Ivory Company. One of the smallest radios at the time at 3-3/4 x 2 x 3/4 inches, it was advertised as The Beaver Baby Grand Vest Pocket Radio Receiving Set.

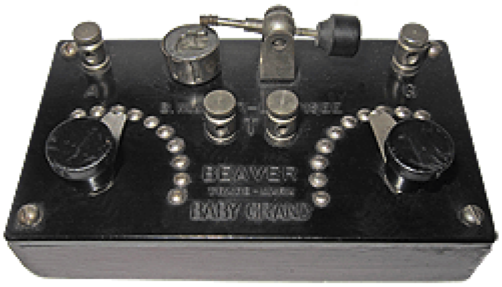
These are shown here in the order they may have been produced based on a progression of part upgrades.



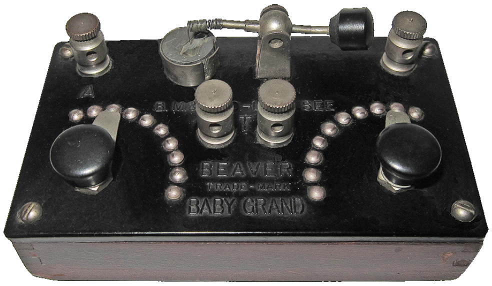
Type 1
Black painted wood case, flat top knobs, small binding posts, simple engraved panel, and no ID of any kind.



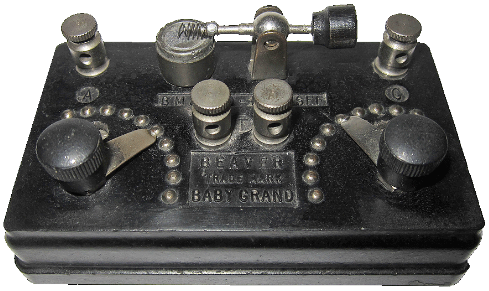
Type 2
Reddish brown colored wood, flat top knobs, small binding posts, simple engraved panel, metal tag on cabinet. (detector arm is missing)



Type 3
Reddish brown colored wood, flat top knobs, small binding posts, raised lettering on panel, no metal tag.

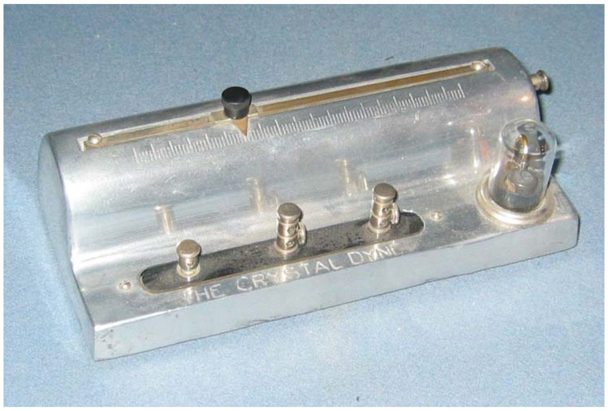


Type 4
Reddish brown colored wood, dome top knobs, large binding posts, raised lettering on panel, no metal tag.

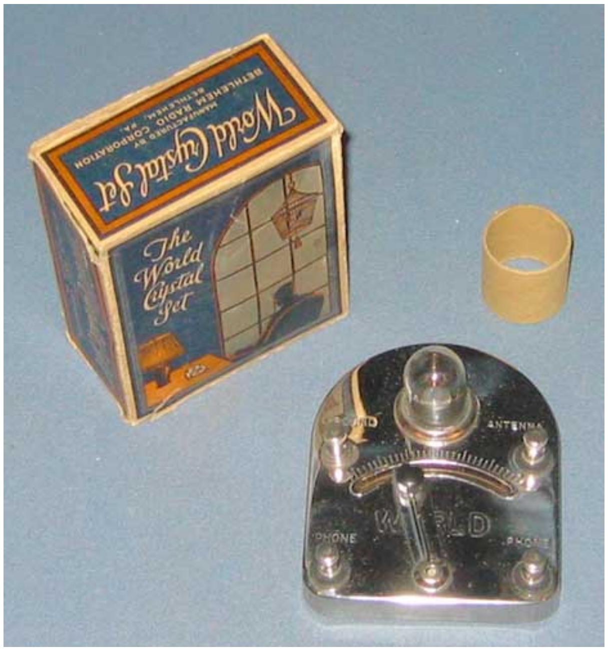


Type 5
Hard rubber cabinet, ribbed knobs, large binding posts, lettering molded into panel. A cover on the bottom protects the coil inside.

Bethlehem Radio Corporation, of Bethlehem, Pennsylvania, made these two metal crystal radios during the 1920s, and may have also made other radio equipment under the BERACO name.

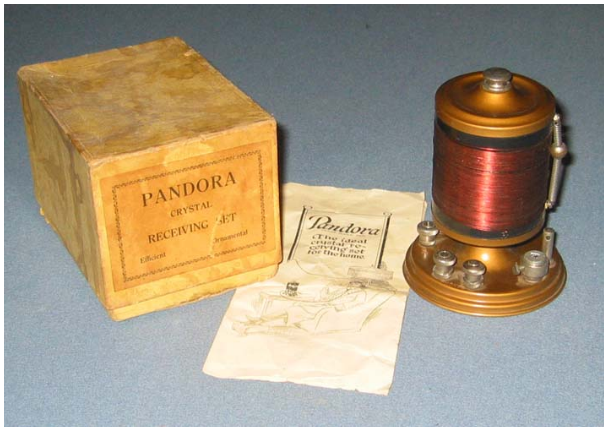


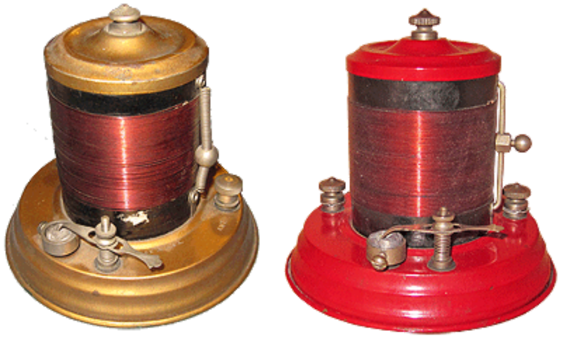
Bethlehem 'The Crystal Dyne'
It has a cast aluminum case, a glass-enclosed crystal detector, and a slide tuner. It is about 8-1/2 inches long x 4 inches deep.

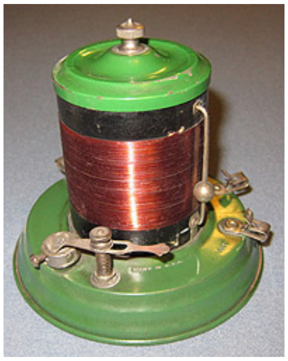


Bethlehem 'World Crystal Set'
It has a nickle-plated metal case, a glass-enclosed crystal detector, and a slide tuner. It measures about 5 x 4 inches. It is shown with its original box. These were also sold painted in various colors including red and green.

BMS Pandora Crystal Set
The Brooklyn Metal Stamping Company, of Brooklyn, New York, manufactured a number of crystal radios in the 1920s, including the 'Pandora' which came in two styles and 4 or 5 colors. This example has the coil raised up on a small pedestal and has the original Russett Bronze paint. It is in mint condition except the detector arm is missing. It is shown with its original instruction sheet and box.

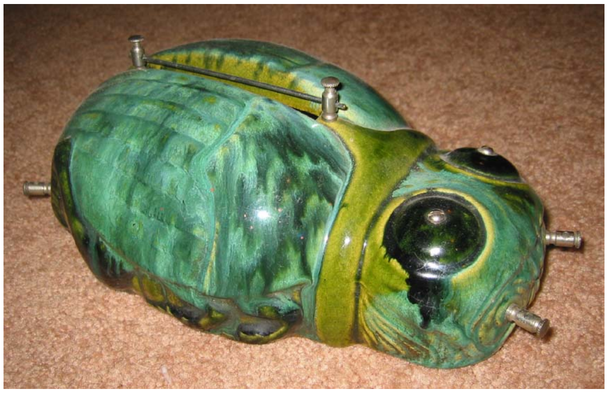




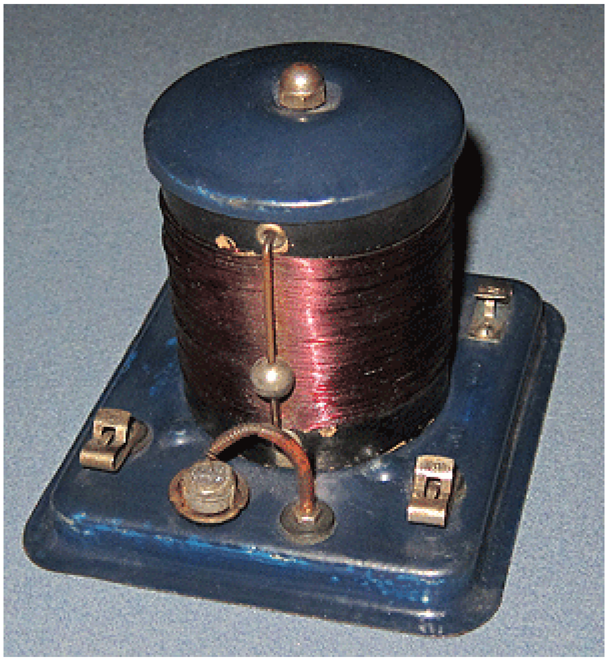


BMS Pandora Crystal Sets
These BMS Pandora sets are styled different from the one above, without the pedestal. Note that the red and green examples have a solid slider bar while the bronze one has a spring, the bronze and green examples have a ball slider while the red one has a slider with a knob.

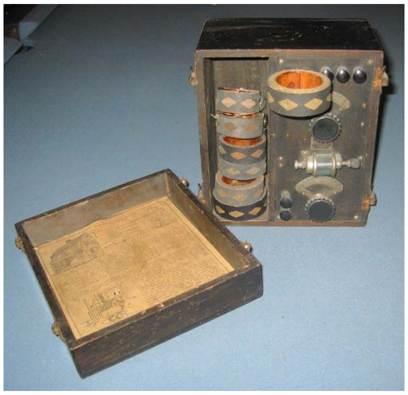
Also, the green example has fahenstock clip connectors while the others have binding posts. The Russett Bronze, red, and Medium Green colors are all original paint.



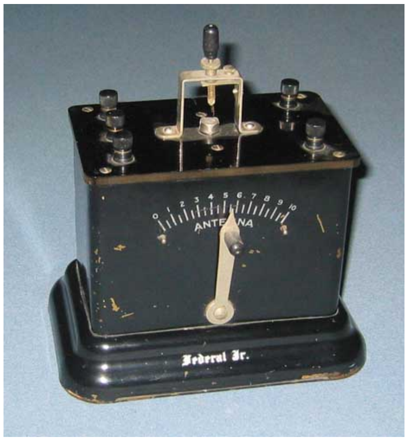
Brush-McCoy 'Mystic'
In 1927 the Brush-McCoy Pottery Company decided to produce a unique pottery item that would appeal to radio fans all over the world, who were then called "Radio Bugs." It was a ceramic bug 9" long containing a crystal radio set. These were called "MYSTIC" Radio Sets. The bug itself is pottery. An article that was in The Zanesville Signal said, "The insulating properties of this material are so high that exceptional reception results."



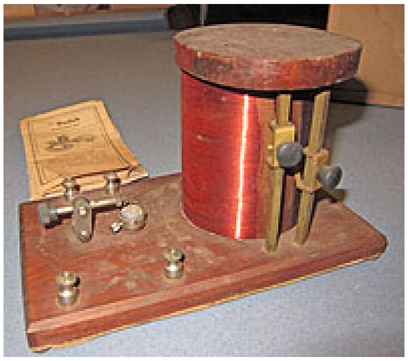
Cannon Ball 'Baby Grand'
1920s crystal radio with metal base.



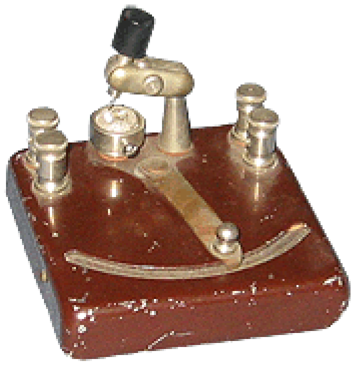
DeForest Everyman
This Deforest Everyman Radiophone Receiver, Type DT-600, was made in the 1920s and used different plug-in coils to receive different wavelengths. It has a glass-enclosed crystal detector.



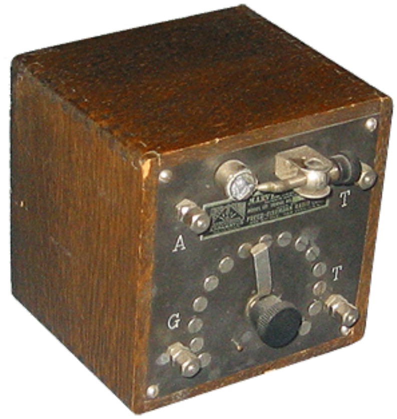
Federal 'Junior'
This Federal Jr. crystal radio was made in the 1920s. The cabinet is metal with a bakelite top. A slider control on one side is labeled 'Antenna', and a similar control on the other side is labeled 'Detector'.



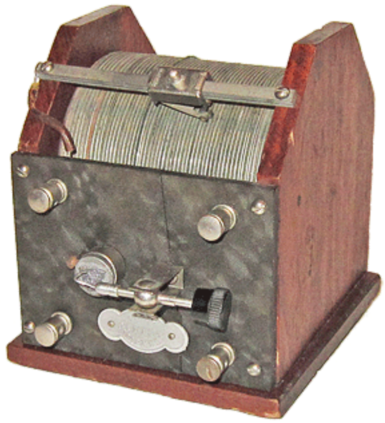
Fletcher 'Radak Wireless Set'
Made and distributed by Fletcher Electric Company at 34 West 36th Street in New York City in the early 1920s. The original operating instructions call this 'The Hand Camera of Wireless! A snappy little Radio Set! Small and light as a postcard camera'.



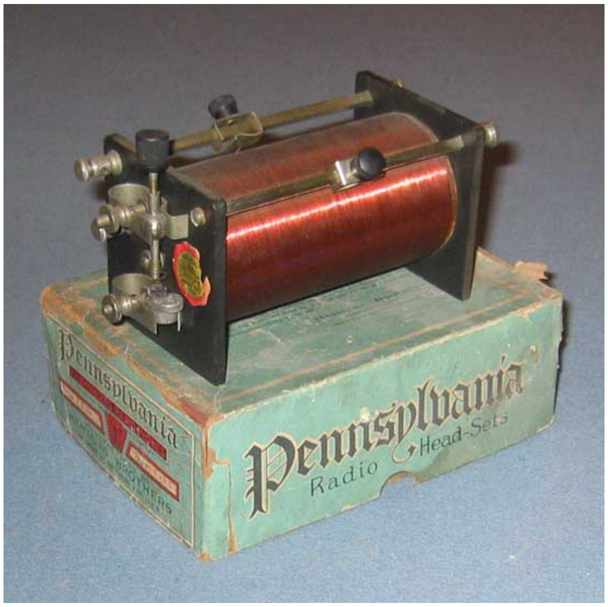
Flivver
This little Flivver crystal radio was made in the 1920s. It has a metal cabinet and is identified as a Flivver on the underside.



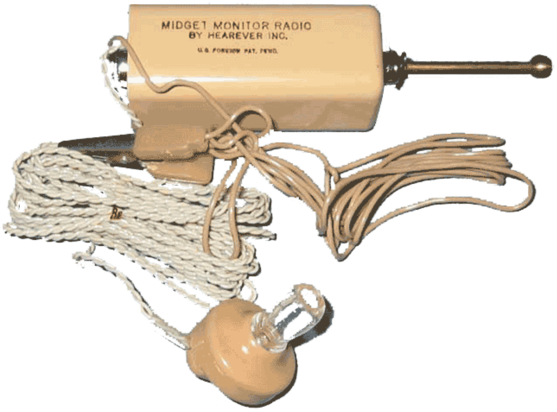
Freed Eisemann 'Marvel 101'
Freed Eisemann manufactured this crystal radio in the 1920s and housed it in a nice oak dovetailed cabinet.



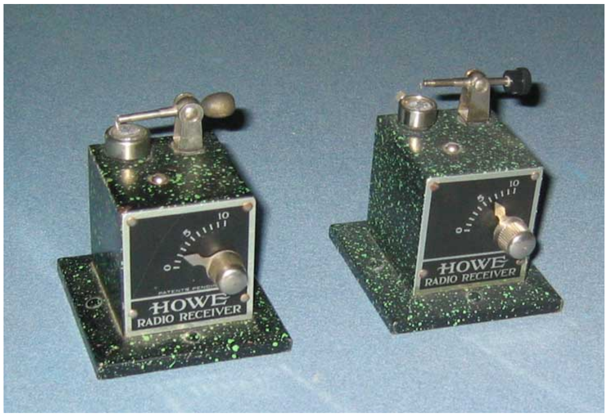
Gillet Marvel
1920s crystal radio



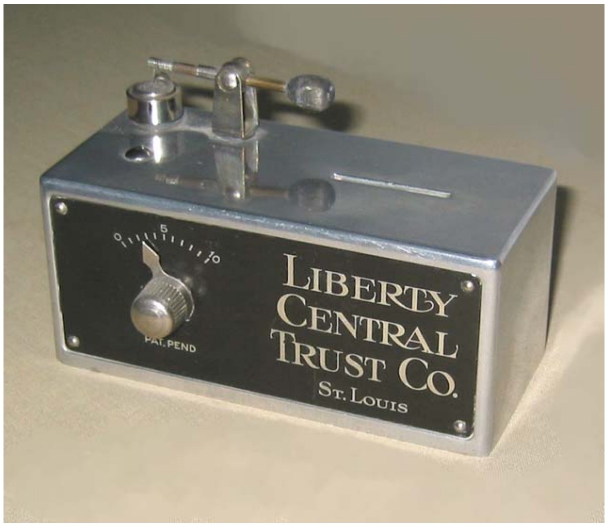
Hamburg Brothers - Pennsylvania
This little crystal radio was sold about 1926 by Hamburg Brothers of Pittsburgh, Pennsylvania, and was endorsed by Radio News magazine. It is sitting on a box of Hamburg Bros. 'Pennsylvania' headphones.



Hearever 'Midget Monitor'
This tiny crystal set was made in the 1950s or 60s and is built into a standard radio IF coil can. Sliding the antenna rod up and down tunes a station. This radio is mint in the original box, and is marked 'MIDGET MONITOR RADIO BY HEAREVER INC.' The instruction sheet gives the company address as: MIDGET MONITOR RADIO, Dept. 150, 623 Marquette Ave., Minneapolis 1, Minn.

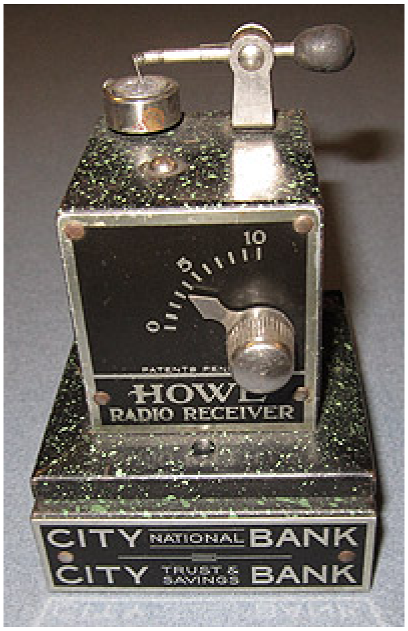


Howe: Early, Late
Two 1920s Howe crystal radios. The left one is the earlier version - it has 'Patents Pending' printed on the front plate, the detector arm has a wooden handle, and the crystal cup is larger.

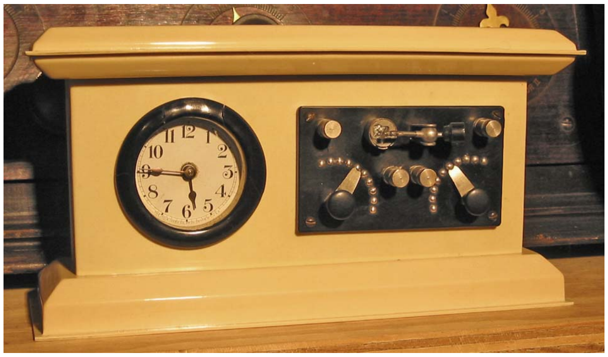


Howe - Liberty Central Trust Co.
This is a bank advertising the Liberty Central Trust

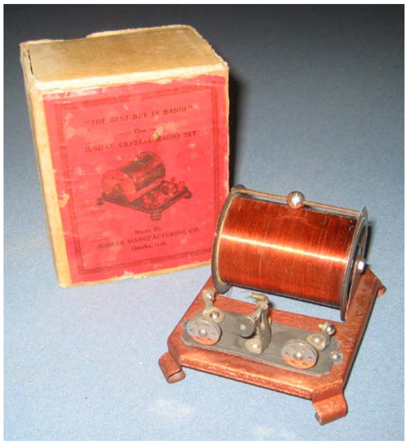
Company of St. Louis Missouri, and it has a Howe crystal radio built into it!



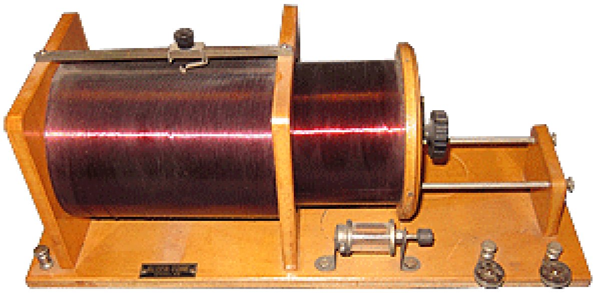
Howe - National City Bank
This is a bank advertising the National City Bank, and it has a Howe crystal radio built into it!



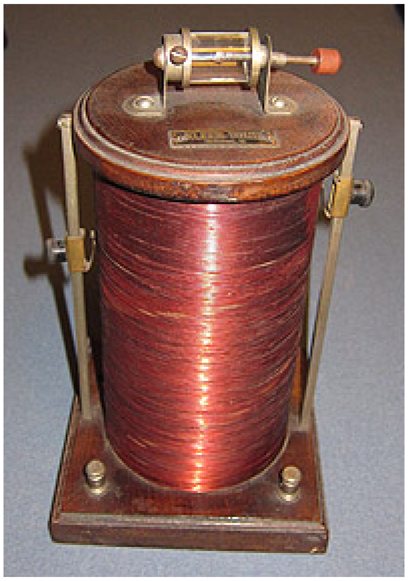
India Ivory
A rare 1920's crystal radio, only documented with a brief reference in the Maurice Siever's Crystal Set books, and a photo in Morgan McMahon's Vintage Radio book, and 1 of only 3 I've seen in collections. This off-white celluloid clock case is inscribed 'Radio Clock Case, India Ivory Co., Pat. Apl'lied For'. The paper face of the wind-up clock is marked 'India Ivory Company, Providence, R.I., U.S.A.' The radio itself looks exactly like an early version of the 1920's Beaver Baby Grand chassis.



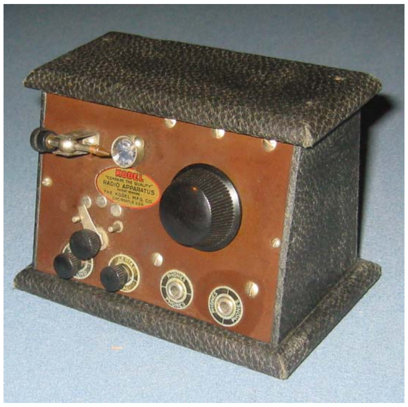
Jubilee
Jubilee Manufacturing Company, which operated in Omaha, Nebraska from 1905 until about 1988, produced this Jubilee Crystal Radio Set in the later 1920's. The red label on the original box proclaims this to be 'The Best Buy in Radio'. Unique connectors allowed up to six pair of headphones to easily be connected to the radio!



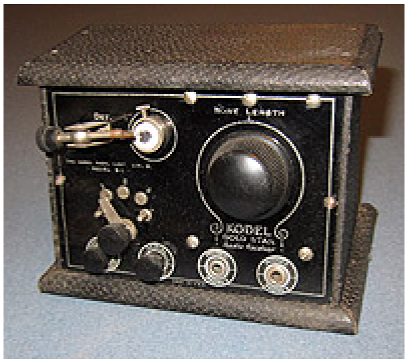
Kleer-Tone Model 100



Kleer-Tone Model B

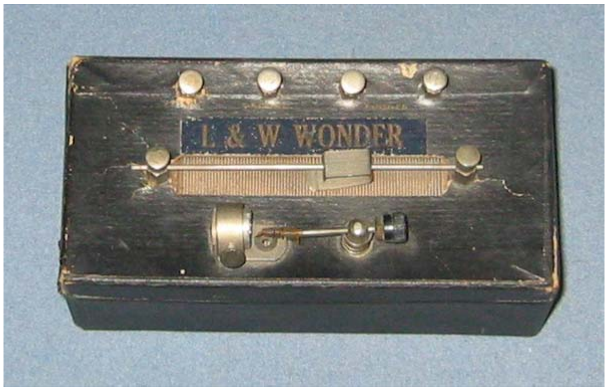


Kodel Model S-1
Kodel's smallest and lowest priced radio, this originally sold for $5.

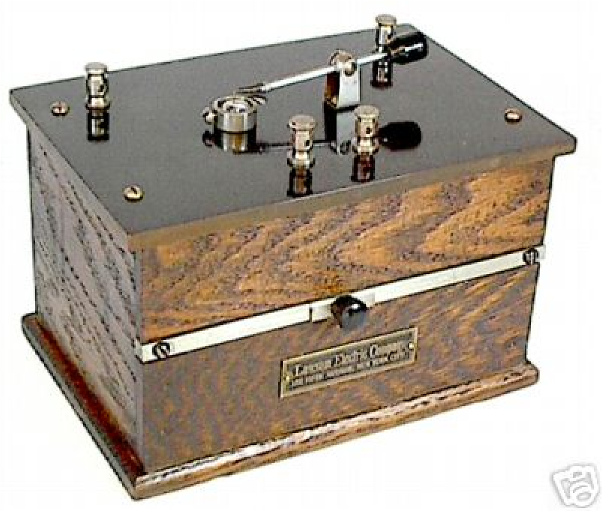


WAVE LENGTH
KODEL
GOLD STAR

Kodel Gold Star Model S-1
Kodel's Gold Star model S-1 is identical to the other version except for the front panel design.

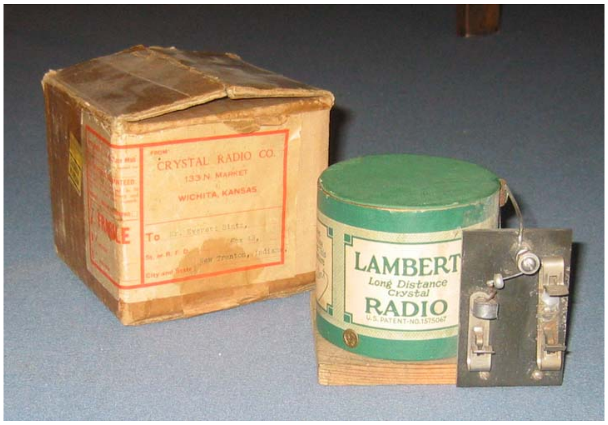


L&W Wonder
A cheaply made crystal radio in a cardboard box cabinet.



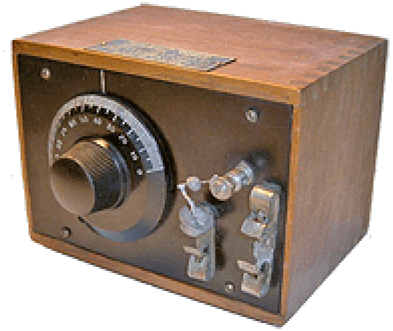
Lawsam Electric Company

Lawsam Electric Company
This 1920s crystal radio was manufactred by Lawsam Electric Company at 122 Fifth Avenue, in New York City. The recessed slider on the front of the cabinet is unique.



CRYSTAL RADIO CO.
133 N. MARKET
WICHITA, KANSAS
LAMBERT
Long Distance
Crystal
RADIO

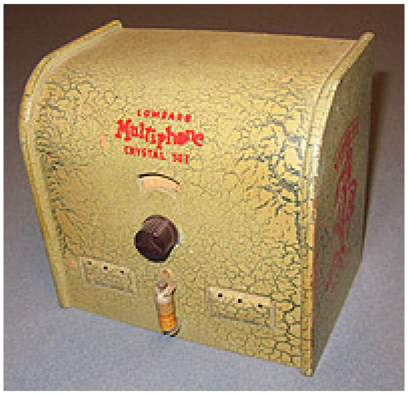
Leon Lambert
This old crystal radio is shown with its original box. It has a very crudely designed detector that looks homemade, but this is original from the factory. It is identical to the wooden version, except with a less expensive cabinet.



Leon Lambert
This crystal radio has a wood cabinet with a brass tag on top saying 'Lambert Radio, Leon Lambert Mfg. Co., Wichta, Kansas'. It is the deluxe version of the green Leon Lambert radio.

Lombard Multiphone
An unusual old crystal radio in a masonite cabinet

painted crackle green with cowboys on the sides. A Lombard detector is mounted below the tuning dial and there are connections for six pairs of headphones! Operating instructions are on the back side and earphone instructions are on the bottom of the cabinet.



LOMBARD

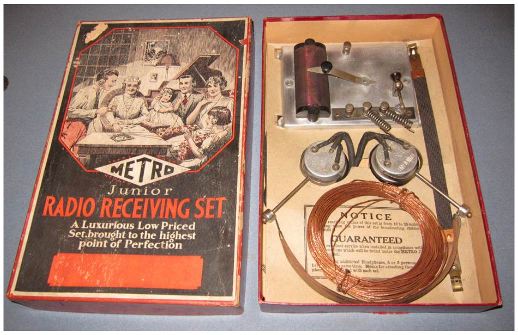
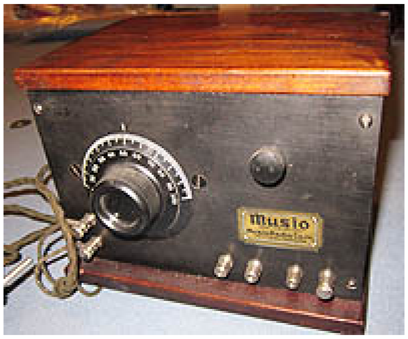
and enough binding posts to connect four sets of headphones. It was made in Newark, New Jersey, and stands 9 inches tall.

1920s, and is shown with its original box. It has a spring-loaded enclosed cats whisker detector.

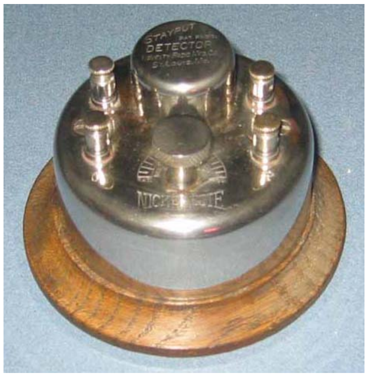


METRO
Junior
RADIO RECEIVING SET
A Luxurious Low Priced Set brought to the highest point of Perfection
NOTICE
GUARANTEED

Metro Junior
A 1920s crystal radio made by Metro Electrical Company in Newark, New Jersey. The same radio was also marketed under other names (see Pal). This is shown in its original box.
The base is aluminum and measures 6 x 5 x 1/2 inch.

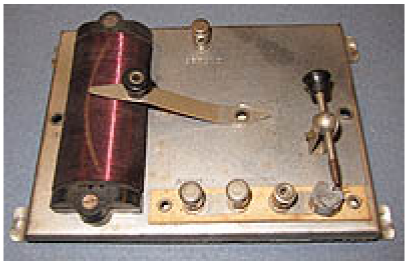


Musio
A 1920s crystal radio made by Musio Radio Company. The small knob controls the internal catwhisker. The lid is held on only by spring clips so is often missing. A pair of Musio headphones completes the set.
It measures 8-1/4 x 6-1/4 x 6 inches.



STAYPUT
DETECTOR
NICKELETTE

Novelty Radio Mfg. Co. 'Nickelette'
A 1920s crystal radio marked 'Trade Mark NICKELETTE'. The detector is under the metal cover marked 'STAYPUT DETECTOR, NOVELTY RADIO MFG. CO., ST. LOUIS, MO, PAT PND'G'. You need to remove the metal cover to adjust the wire cats whisker. Directions are on a paper label on the bottom of the radio.



Pal
A 1920s crystal radio made by Pal Radio Company in Jersey City, New Jersey. The same radio was also marketed under other names (see Metro).
The base is aluminum, has a cardboard instruction card riveted underneath, and measures 6 x 5 x 1/2 inch.

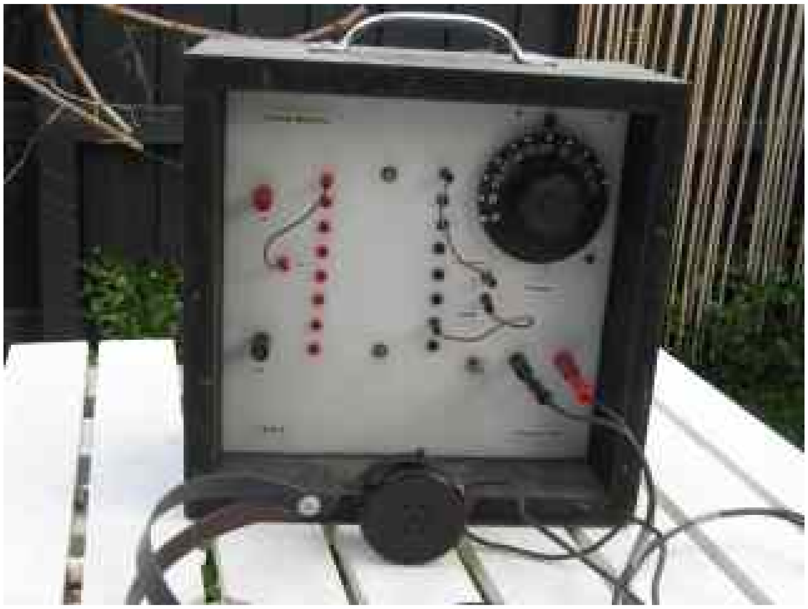
Return to VK3YE amateur radio projects

A simple crystal set for free power radio

Of any electronic project, the crystal set would have to rate as one of the most popular. Many amateurs are on the air today because of their early construction of a crystal set. Most practical electronic books for beginners include at least one crystal set project. Unfortunately, some of these circuits take simplicity too far and deliver mediocre performance, often by omitting key components such as the tuning capacitor, or failing to provide coil taps.



This article describes a crystal set of medium complexity. It features coil taps for the antenna and diode to make it useful for both country and metropolitan listeners. The taps allow the set to cover 160 metres if desired. All parts are easily obtainable, making it a good choice for the beginner. The endless possibilities for experimentation also make crystal sets interesting novelty projects for experienced constructors. The schematic is shown here:

(from Amateur Radio February 2001, page 20)

Obtaining the parts

Tuning capacitor

A large air-spaced type, covering about 10 to 415 picofarads is preferred. These capacitors were common in valve and early transistor radios and often appear at hamfests. Their long shafts make it easy to attach large tuning knobs. When purchasing one see that the shaft turns freely, but is not loose. Ensure that the plates are straight and do not touch when meshed - use a multimeter (preferably with audible continuity function) to test this. Avoid capacitors with 3/8 inch shafts unless nothing else is available â€“ knobs for these are not obtainable, and an old valve radio dial drum will need to be used instead.

If a large capacitor is unavailable, a small plastic dielectric unit is suitable (such as stocked by Jaycar and online). The lower maximum capacitance (160 pF) means that more coil turns are required to provide coverage of the lower end of the broadcast band. This can be partially overcome by connecting the 60 and 160 pF sections in parallel (link the 'A' and 'O' tabs). The main disadvantage of these capacitors is their short shafts, which makes it harder to attach most types of knobs.

Vernier Drive and dial

The use of a vernier reduction drive is not necessary. However, its inclusion makes tuning easier, particularly on the higher frequencies. These are rare new but sometimes come up at hamfests. If your drive lacks a dial, one can be fashioned from a plastic or metal disc, such as a jar lid or salvaged computer hard disc. Glue the dial directly to the skirt of the tuning knob if you lack a vernier drive.

Diode

This is the most easily obtainable and cheapest component in the project. A germanium diode, such as a 1N60, 0A90, 0A91, 0A95 or 1N34A will be suitable. The purists still make their own diode detector with a 'cats whisker' and lump of galena, but modern diodes provide more stable and repeatable performance.

Headphones

The very old high impedance headphones are required for this circuit. A minimum of two kilohms is suggested. Medium impedance headphones (approx 600 ohms) will also work, but are less sensitive.

High impedance headphones have become difficult to obtain. Alternatives include:

1. Old-style telephone earpiece. Quite sensitive. Found in the old Telecom corded phones.

2. Crystal earpiece. These are sensitive, easy to obtain and inexpensive. You may need to connect a 100k - 470k resistor in parallel for it to work properly.

3. Piezo transducer. Believe it or not, these actually will work as an earphone. Some sizes even fit snugly in the outer ear in a similar manner to modern earpieces, such as used with mobile phones. The main drawback with transducers is their peaky audio response. Â In some cases it may be necessary to wire a 100k - 470k ohm resistor across the earphone connections for correct operation.

4. 1k to 8 ohm audio transformer and standard low-impedance headphones. Works well, but not as sensitive as a crystal earpiece.

5. Cheating! Use a transistor or IC amplifier kit to run a speaker. This approach eliminates the 'free radio' advantage of the crystal set, but provides louder reception in weak signal areas and allows speaker listening.

Coil and Coil former

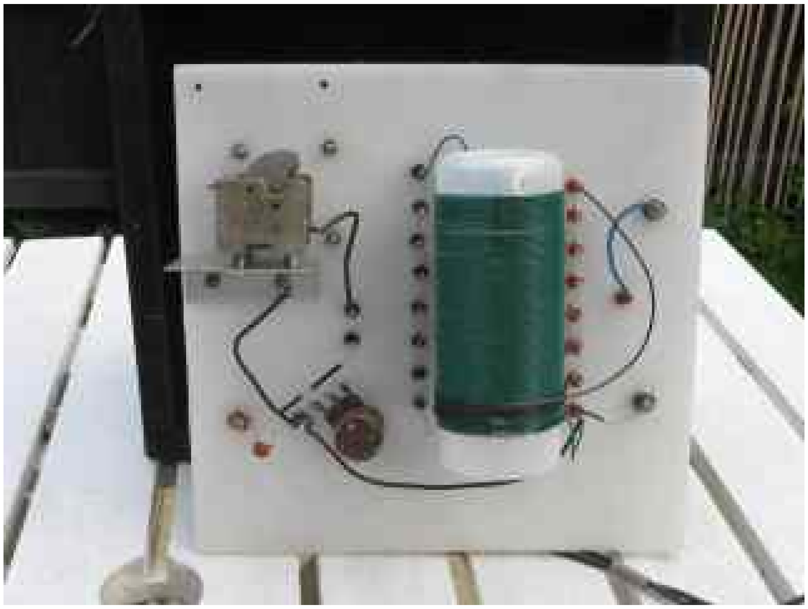
This needs to be a cylinder about 55 millimetres in diameter and 150 mm long. The length needs to be long enough to accommodate all ninety coil turns used, with enough left over for mounting to the front panel. Plastic pipe, shampoo container or similar will suffice. Though enamelled copper wire can be used for the winding, the prototype used thin plastic-covered stranded insulated wire.

Front panel

All parts are mounted on a 6mm-thick polyethylene chopping board, which forms the front panel. A hacksaw was used to cut the panel to fit inside the wooden case. Use the thinnest chopping board available so that the many screw-mounted sockets used can be fastened properly. The front panel pictured was cut to 240 mm square.

Case and handle

Use non-metallic material for the enclosure. The box used in the prototype was originally a speaker bought cheaply at a school fete. The lid (which held the speaker) was removed, and the rest of the box painted. The top carry handle is optional and came from a hardware store.



Construction

Commence construction once all components have been obtained. Plan how the parts will fit behind the front panel. The diagram and pictures above show the arrangement used in the prototype. The coil is fastened with stand-offs and the variable capacitor is screwed to an aluminium L-shaped bracket. 4mm binding posts with banana sockets are used for the antenna and headphone connections, and 2mm micro sockets for the coil tapping points.

Start by winding the coil. This consists of ninety turns of thin stranded insulated wire close wound on a plastic tube approximately 55 millimetres in diameter. A large number of tapping points are provided so that the user can vary the set's frequency coverage, and antenna and diode coupling. This makes it possible to obtain the best compromise between volume and selectivity for a particular station.

Figure Two shows the coil construction. Start from the earth end (identified as '0' in the diagram). Make two holes in the former to anchor the end of the wire. Wind six turns and then an extra half-turn. With a knife remove about 1cm of insulation, taking care not to cut the wire. Form the bare wire into a loop and lightly coat with solder. Do not apply excessive heat - the wire insulation easily melts. Wind another five and a half turns and make another tap. Repeat for the remainder of the coil until approximately ninety turns have been wound. Add more turns and taps if using a smaller variable capacitor than specified. Again make two small holes in the former to anchor the wire.

Place the completed coil aside and start work on the front panel. Mount the 4mm banana binding post terminals for the antenna, earth and headphones, as shown in Figure Two. Drill holes and mount the 2mm terminals for the coil taps and the antenna, diode, variable capacitor taps. The tuning capacitor can also be fastened at this time.

Two sets of screws and spacers can be used to mount the coil to the rear of the front panel. A 10mm separation between the coil and the panel is adequate. Solder in the various components and connecting wires as per Fig 2. Use insulated wire for the connections between the sockets and to the variable capacitor. Tinned copper wire can be used for the short links between the coil taps and the 2mm sockets. Use insulated wire for the three jumper leads. The jumpers should be sufficiently long to be able to make connections with all taps along the coil.

This completes the construction. The panel can now be inserted into the box. In the unit pictured, the front panel is recessed â€“ this protects the banana sockets and dial and makes the set more rugged. It also allows attachment of a hinged lid if required.

Parts List

* 10 â€“ 415 pF variable capacitor x1 (see text)

* 0.001 uF disc ceramic capacitor x1

* 1N60 germanium diode x1

* Vernier dial or drive x1 (optional)

* 2mm micro socket x19

* 2mm micro plug x6

* Banana socket (red) x2

* Banana socket (black) x2

* Insulated wire 20m

* Tinned copper or bell wire 1m

Other items: case and handle; polyethylene chopping board; Coil former â€“ 55mm dia, 150 mm long; screws, nuts, washers and spacers; mounting bracket for variable capacitor.

How it works

To receive signals, a radio circuit must perform three functions: selection, detection and reproduction.

The inductor and variable capacitor form a tuned circuit. The role of the tuned circuit is to select one of the many signals present at the antenna. The size of the inductor and capacitor determines the frequencies that can be tuned. The capacitor is made variable to allow the full range of AM broadcast band frequencies (531 to 1602 kHz) to be received.

The diode detector converts the selected radio frequency signal to an electrical current varying at audio frequencies.

The headphones convert this audio frequency energy to sound. The principle is similar to a relay â€“ the signal cause current to flow in a winding that forms an electromagnet. The magnetism generated vibrates the metal diaphragm, thus creating sound. Crystal earpieces perform the same function, but rely on the piezo-electric effect.

Unlike in a conventional radio, which uses amplifying devices such as transistors and integrated circuits, crystal sets are powered by the signal from the incoming station, so no batteries is required. If provided with an efficient antenna and earth, crystal sets can receive signals thousands of kilometres away.

Antenna and earth

A crystal set requires a wire antenna to operate properly. The longer and higher it is the better. A length of at least 10 metres in urban areas, and 20 â€“ 30 metres elsewhere should provide reception in most cases. The antenna should always be installed away from power lines for safety reasons and to reduce interference pick-up. An existing amateur or TV antenna can also be effective, especially if the coaxial feedline is used as part of the antenna. This is achieved by connecting both the outside and the inside of the coaxial connector to the receiver's antenna terminal.

An earth provides stronger signals, and is essential in remote areas. In homes with copper water pipes, this can simply be a lead to the nearest cold water tap. In newer homes, where plastic pipes are used, an outside ground stake can be used instead.

For long distance reception (hundreds or thousands of kilometres) more than usual effort needs to be taken when installing the aerial and earth. Reference One suggests a length of about 100 metres and a height of at least 12 metres. A series of buried radials is suggested for the earth, rather than the water pipe suggested above.

Operation

Connect antenna, earth and earphones. Install the three jumper leads. Set the capacitor tap to near the top of the coil (either the 78th or 90th turn) and the diode and antenna taps to approximately midway along the coil.

In a quiet room, adjust the tuning control and listen for a station. If several stations are audible, move the diode or antenna taps nearer the earth end (lower numbered turns) of the coil. This increases the set's selectivity and makes it possible to separate stations. In a capital city it should be possible to separate at least nine or ten stations. Optimum tap settings vary across the broadcast band â€“ lower frequency stations are often best received with higher tap settings. In rural areas volume is normally more important than selectivity, so the taps can be moved near the top of the coil.

Reception of AM operators on the 1.8 MHz (160 metre) amateur band is possible by moving the capacitor tap lower down the coil, to the 54th or 66th turn. Performance will be well down on a superhet or regenerative receiver, and SSB signals cannot be resolved. Whether you hear amateurs or not depends on your antenna system and the extent of activity from nearby operators. Here in Melbourne 160 metre AM activity includes the Monday to Saturday AM morning net starting at 11am.

In many areas there are narrowcast stations between the top of the official AM broadcast band and 160 metres. Because of their low power these stations will be weaker than the mainstream broadcasters. However these stations are excellent tests of your receiver and antenna system.

Video demonstrations of this project

Conclusion

A crystal set of moderate complexity has been described. It is the minimum required to provide good reception of local stations in urban and rural areas. However numerous refinements to increase sensitivity, selectivity or audio output can be made. These include:

1. Double tuned circuits (with variable coupling between them) to improve selectivity

2. Use of a tuned trap to null out interfering signals

3. Attention to the construction of coils to provide the highest possible Q

4. Addition of an impedance matching network to provide efficient power transfer between the antenna and the tuned circuit

5. Use of a large loop antenna for the coil to allow reception of signals without an external antenna and nulling of unwanted signals

6. Voltage doubler diode detector circuit using two diodes to increase volume

7. Use of DC bias (from a DC voltage applied to the diode) or RF bias (from a locally generated RF signal on the receiving frequency) to improve sensitivity, or, in the case of the latter, to provide CW and SSB reception.

8. Use of a Q multiplier to increase sensitivity and allow CW and SSB reception.

Should you decide to experiment with these changes, it would be desirable to keep this set as a reference and build a second receiver as a test bed for the experiments.

Obtaining the parts

Suitable parts were discussed in detail above. Many if not all can be bought online, with examples presented below.

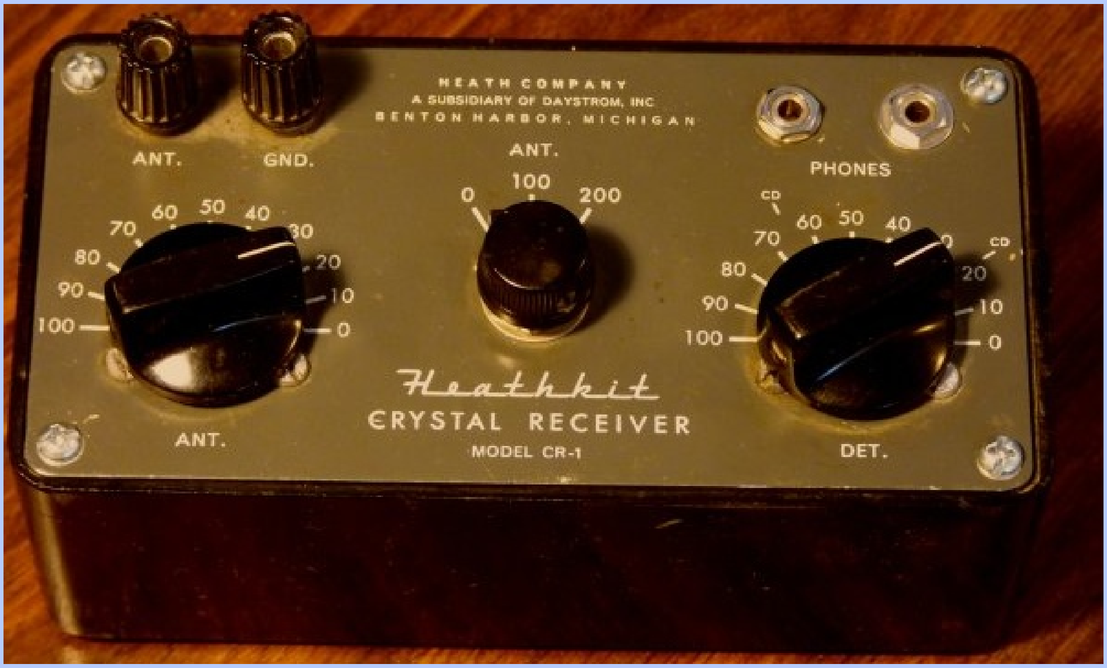
John Fuhring

If you found this page while looking for a simple, but great performing little radio that you can build yourself, you might be more interested in reading about

An Armstrong "Crystal" Radio

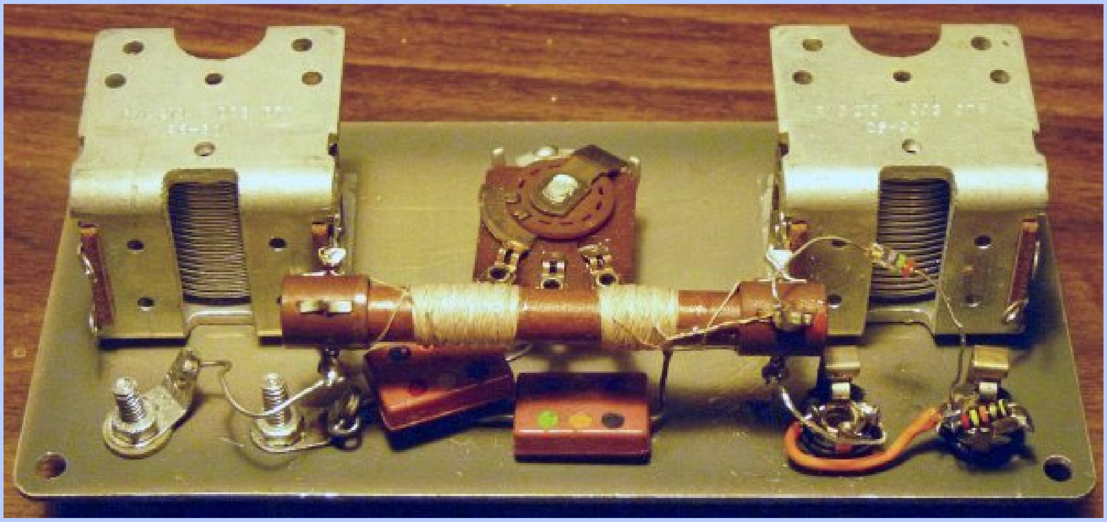
Rebuilding my Heathkit CR1 and getting it to work

I can not really remember when or how I came by this little radio, but it was many years ago. I seem to recall that I picked it up cheap at a thrift store as a non-functional item that had been poorly or incompletely put together. I remember that some of the screws and a connection post was missing and the parts weren't soldered in properly or correctly. To tell the truth, I didn't know how the radio was supposed to be wired and I must not have been very interested in getting it working, so it sat in a cabinet for several years until a year or so ago.



My CR-1 crystal radio modified for two earphone jacks.

About a year ago I came across the little radio and decided that I would figure out how it was supposed to work and then I'd put it together correctly. The first thing I did was put a sub-miniature phone jack in place of the missing binder post since my piezo earphone has a sub-miniature plug on it and besides, I didn't have a matching binding post to replace the missing one. I took off the grounded binding post and put a screw to cover the hole. Next I soldered the antenna tuner coil to its variable capacitor and wired the two fixed capacitors to the selector switch. I then soldered the station tuning coil side to its variable capacitor and from the tap on the station tuner coil, I soldered a 1N34 germanium detector diode to the phone jack. By the way, Heathkit called the tuning capacitor connected to the station tuning coil the "detector tuner" and on the panel it is labeled as "DET" for detector.



Back side showing the radio's components.
The antenna and the station tuning coils are wound on the phenolic tube. The antenna coil is to the left of center. A powdered iron (ferrite) slug is inside the tube between the two coils.

When I finished soldering everything in correctly, I connected the little set to my antenna & ground and soon I could clearly hear my local AM stations, but I noticed that the tuning dial seemed to be way off. At the very top of the AM dial (around 1600) I know there is a very strong Mexican station, but I couldn't go high enough to tune it in. To match the dial with the AM band, I took a thin wooden stick and gently pushed on the ferrite slug in the coil form until it was nearly centered between the two sets of coils. By moving the slug, I was able to match the dial to about where I knew my local stations were and was able to hear the Mexican station near the top of the dial. The slug is held inside the tube by wax and if you are careful and apply slow, even pressure, the slug will move to where you want it.

I now had a crystal radio put together as it should be and it worked -- sort of. Below is the schematic diagram I developed for the little radio. I'm kind of big on schematic diagrams, but I wasn't always so.

My schematic diagram of the Heathkit model CR-1 crystal radio.

In many respects, this design operates on similar principles to the "Trench Radios" of WW 1. Military radios of that day, such as the US

Army's BC-14/SCR-54, also used antenna tuning, light coupling between stages, a tuned diode section and they operated on the same range of frequencies, 550-1600 KHz.

I understand that these kits were very popular with Boy Scouts and were marketed as a kind of a "Survivor's Radio" during the worst parts of the "Cold War" when my government's Civil Defense planners expected an Atomic War with the USSR to break out at any time. With only a few CONELRAD stations on the air and with us few survivors trapped in "bomb shelters" for months and years, with our entire civilization and economy wrecked, still, news and information would be available to any doomed citizen having one of these radios, even though there was no electricity and the battery operated radios had all gone dead. Doesn't that sound cozy? Doesn't that sound like fun? Well, at least we would be "better off dead than red" and, being dead, we'd not have to "live under godless communism."

Oh, weren't the "Good Old Days" just wonderful?!?

At the time I first got this little radio working, all I had was a short outside antenna that I used with my one-tube regenerative radio and my EC-1 shortwave radios. To tell the truth, when I connected the Heathkit crystal radio up to my rather poor antenna, I was very much UN-impressed with this radio. Compared to my Armstrong regenerative radio (written about elsewhere on this website), it performed very poorly and all I could receive was my four really strong local AM stations. You know, there is nothing on my local AM radio except all this mean, downright goofy, unpatriotic right-wing hate talk or the even more disgusting and ignorant Fundamentalist preaching, none of which I can stand to listen to, but there is a Mexican music and local talk station that wouldn't be bad if I understood a word of Spanish. With nothing to listen to, I lost interest and did nothing more with the radio.

Surprising performance from this kind of radio

A few weeks ago I vastly improved my outside antenna and had some fun using it to do some AM DX listening with my 1958 Armstrong one tube regenerative radio. One evening, a few days ago, the AM signals were coming in from San Francisco, Los Angeles and Reno very strongly and so I started wondering if the crystal radio could pick them up too. I was very skeptical because the crystal radio had never performed all that well, but now I had a better antenna and maybe things would be different.

When I connected the crystal radio to my long wire antenna, I was pleased to discover that both the station tuning AND the antenna tuning sections now worked together to make the tuning very sharp. Before, with the short antenna, the antenna tuning section didn't seem to do anything and I was wondering what it was put in there for, but now it worked and I was extremely impressed with how selective the radio could be for a crystal set. Strong stations that had once blended together now could be separated and the strong stations didn't bleed on to the weaker stations. So, with the radio working better than at any time since I rebuilt it, I tuned to about where KGO up in San Francisco should be (middle of the dial at 810 KHz). Wow! by carefully adjusting both tuners, I could hear KGO loud and clear and without other stations overlapping. By the way, KGO is about the last station on AM that hasn't been taken over by the right-wing propagandists or America's own brand of the Talaban and they feature real people talking about real things that matter to people and not the steady diet of political and religious garbage that dominates nearly all of AM these days. Sadly, when KGO goes silent, I'm sure someday it will, AM radio will be well and truly dead.

Listening to this simple little radio pull in distant stations like that was a kind of "radio communications epiphany" for me. I always wondered how ships like the Titanic could communicate with other ships and to shore stations with nothing more than Fleming Valve or crystal radio receivers. My experience with this little radio has shown me how, with a good antenna and good sharp tuning circuits, individual radio signals can be picked out from a mass of signals out there and can be heard from a long way off. For me, this is a very wonderful thing, especially when I consider that these radios do not amplify their signals, but use the tiny electrical energy that is picked up by the antenna to make sound. Such is the extreme sensitivity of human hearing and the amazing efficiency of the circuits, detector crystal and earphones that microwatts of power, originally coming from a station hundreds of miles away and landing on my antenna wire, can be heard clearly.

The way this radio works is as basic as it is possible to get

and here's how it all works:

Imagine that there is a radio station 10 miles away and that it that is broadcasting radio waves at 1,400 KHz. Imagine that our radio station is broadcasting hundreds of watts of energy into space and that if we could capture just a tiny amount of this energy, we would be able to hear what was being broadcasted. Imagine that we have a crystal radio like the one above connected to a long wire antenna.

(1) The passing radio wave from our station induces a tiny high frequency voltage on our antenna wire. The antenna is connected to the antenna coil (coil on the top of the diagram) with its antenna tuning capacitor to the left and below it.

(2) When the antenna capacitor is tuned just right so that the inductance of the coil is matched by the capacitance of the tuning capacitor, a tiny current from the antenna flows in the antenna coil to produce an oscillating (or varying) magnetic field inside the antenna coil. By carefully adjusting the antenna tuning capacitor, this oscillating magnetic field will be right in tune with 1,400 KHz and 1,400 KHz only. This is important because it helps seperate our 1,400 KHz signal from all the others on the AM band.

(3) The oscillating magnetic field inside the antenna coil is coupled over to the other coil (the station tuning coil) through the well known principle of "Mutual Inductance" discovered by Michael Faraday in the 1830s.

(4) The 1,400 KHz signal that has been coupled to the station tuning coil is contained in a "tank circuit" that is made up of the station tuning coil and the station tuning capacitor (shown to the coil's right).

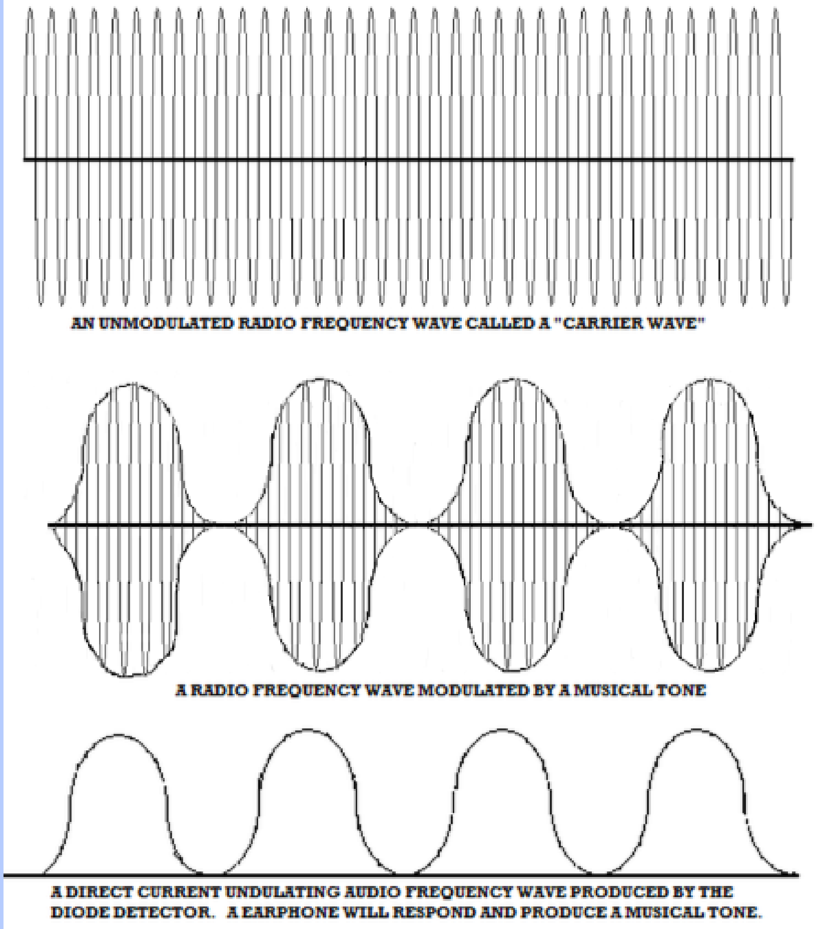
(5) By carfully adjusting the station tuning capacitor so that its capacitance exactly matches the coil's inductance, a so-called tank circuit is formed. This tank circuit "resonates" or "tunes in" the 1,400 KHz signal and that means that it further seperates our 1,400 KHz signal from all the other nearby signals. We now have just the radio signal we want, but we need to do more because it is impossible for our ears to hear radio frequency signals.

(6)
To "detect" the presence of the radio frequency signal that is resonating in the tank circuit, some of the tank's energy is tapped off near the bottom of the station tuning coil and it is wired to one side of the 1N34 detector diode.

(7)
The 1N34 diode chops off the negative part of the radio frequency wave. The detector needs to do that or the negative part of the wave would cancel out the positive part of the wave and nothing would be heard.

(8)
When the diode detector chops off part of the radio frequency signal, direct current audio frequency undulations are all that are left over from the original radio wave. These direct current audio frequency undulations correspond to the sound being transmitted by the station and when the wires of a very sensitive earphone are connected to the detector, these undulations of direct current cause the mechanism inside the earphone to vibrate in step with the undulations and it is those vibrations that we hear as sound.

Here is a graphical representation of what's going on when a radio frequency signal is detected (turned into sound):



AN UNMODULATED RADIO FREQUENCY WAVE CALLED A "CARRIER WAVE"

A RADIO FREQUENCY WAVE MODULATED BY A MUSICAL TONE

A DIRECT CURRENT UNDULATING AUDIO FREQUENCY WAVE PRODUCED BY THE DIODE DETECTOR. A EARPHONE WILL RESPOND AND PRODUCE A MUSICAL TONE.

Graphs of the various waveforms seen at the tuner stage (top two) and at the detector stage. Unmodulated carrier waves are also called "continuous waves" and can't be heard by a crystal detector except as a kind of a very faint hissing noise. AM radio stations try to avoid sending out unmodulated carrier waves (called "dead air") and so this waveform is rarely seen. More common is the waveform showing lower frequency sound waves superimposed on the carrier wave.

The dark black line is where the voltage is zero as a carrier wave crosses from positive to negative. As shown here, the negative going parts of the wave are stopped by the detector diode so that positive to zero to positive undulations remain. If you reverse the diode, the direct current undulations will be negative to zero to negative, but the same musical tone will be heard in the earphone.

Most crystal radios use only one half of a radio frequency's wave.

The importance of a good antenna and ground system

These radios are not connected to your house's AC power and they use no batteries. A crystal radio has no amplifying circuits and yet they output sound and sound is energy. Where do they get the energy to make sound? Do they somehow use mysterious and occult "free energy from space" or something goofy like that? The energy needed to run these radios doesn't cost you anything directly, but it isn't free or mysterious. The energy is from a tiny fraction left over from the hundreds of watts of radio frequency energy a station broadcasts out to space. The vast, vast majority of the energy a broadcast station radiates out of its antenna system is lost, but a tiny fraction of it may be picked up by an antenna at somebody's house.

Antennas for listening to AM stations can range from tiny "loop" antennas that are extremely inefficient, but good enough for amplified radios, all the way to elaborate "long wire" systems dozens and dozens of feet long and high up in the air. The general rule was discovered by Marconi over a hundred years ago that the longer and higher the antenna, the better it is at capturing some of that energy that is passing by. To produce enough energy so that it can be processed inside the crystal radio circuits and then come out as sound energy strong enough to vibrate the mechanism inside the earphone, the antenna needs to be as long and as high as is practical. Practical is what you have room for and how high you can safely go. Practical antennas can be strung between poles located at the ends of a roof or from the house out to a distant tree or pole. It is true that antennas longer than 60-100 feet and higher than 25 feet do capture more energy, but things soon get very difficult and for very little extra gain at distances and heights beyond what is practical.

In addition to a really good long wire antenna (as long as is practical as mentioned), this radio must have a good ground. Right now, I am using my house's wiring as a ground and it seems to work well. Water pipes, when available to connect to, are supposed to work even better. When using house wiring, it would be a deadly mistake to connect to anything but the AC ground, so be careful.

Sensitive, high impedance headphones or earphones are a must

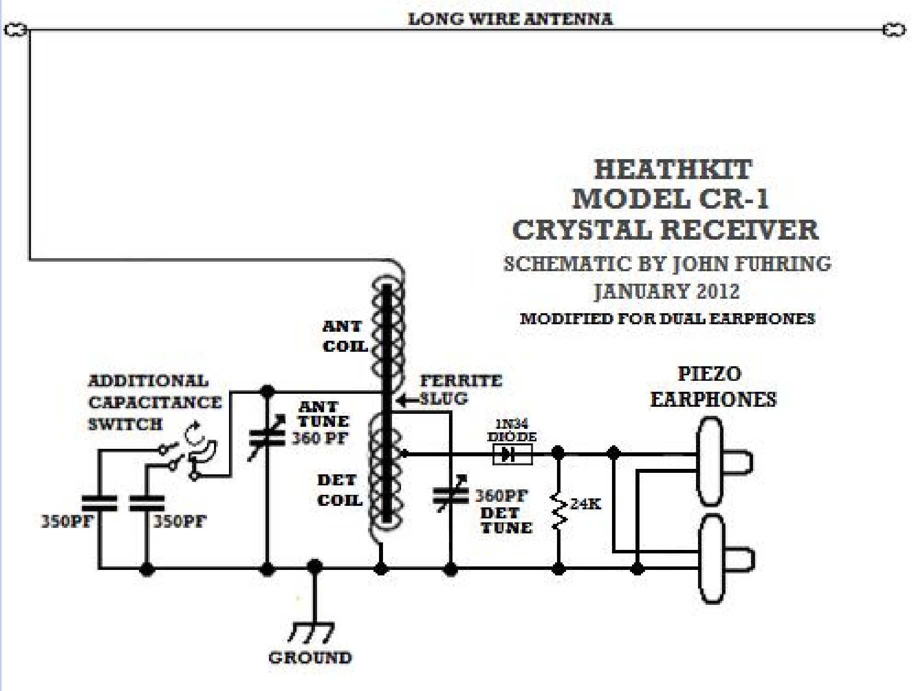
This radio works reasonably well with good quality high impedance headphones, but my very inexpensive piezoelectric earphone is noticeably louder on weak signals. The tapped tuning coil matches high impedance headphones, but for best selectivity (ability to separate close-by stations), the even higher impedance piezoelectric earphone works best.

A modification so I can use two earphones

After using this little radio set for several days, I had a "brilliant" idea. Since only one side of the radio frequency wave is being "detected" (or rectified) and being turned into undulating direct current waves, what about the other side of the radio frequency wave? Couldn't I detect it too, only in reverse and end up with two direct current waves of opposite polarity so that I could connect up separate earphones? Sure, why not, so that's exactly what I did. I installed a second phone jack and a second 1N34 diode only the new one is in reverse of the other. Then I did some testing and even more testing today. I hate to admit it, but the truth is, I can barely detect a any real difference between using a separate detector and just connecting the second earphone to the same diode. By the way, I noticed some "rattling" on the stronger signals while having two earphones connected, but when I put 24,000 ohm (1/4 watt) loads across the earphones, the tuning didn't seem to be effected, the sound quality improved and the "rattle" was gone.

When I first tried this dual diode system out, there seemed to be a real improvement over using two earphones off the same diode, especially on really weak signals, but on further testing, that difference appears to be minimal at best. At first I was surprised that I had never seen or heard of anybody doing this back in the early days of radio when family members would share a headphone, but now I'm not so sure this is a good idea after all. The theory looks good, but in practice, it's hardly worth doing.

Here's what the circuit now looks like with two earphones connected to the same diode:



The Heathkit CR-1 modified for two earphones.

Even though using an extra diode didn't really improve the operation of my crystal set as much I thought it would, I liked the idea of having an extra jack for another earphone so I installed it. I can now share my radio's output with somebody else in the bomb shelter in case Atomic War breaks out. Doesn't THAT sound like fun? Seriously, listening with both ears improves my listening experience -- now if there was just something worth listening to.

Tuning this radio for maximum sensitivity and selectivity

The trick to tuning this radio is to first locate a strong local station of known frequency and tune it in with both the antenna tuner and the station tuning controls. If the setting of the antenna tuning control doesn't seem to make much difference, try switching in extra capacitance, but if that doesn't help, consider stringing up a longer antenna. Both controls should be used to peak the signal for maximum loudness. Once you have an idea where on the dial your station is located, move both controls to about where you guess the weaker station you want to listen to might be. Once there, slowly and carefully adjust the station tuning until you hear something and then peak it up with the antenna tuning control. You may have to go back and forth a few times to get maximum volume with minimum interference from nearby and stronger stations. The radio has a switch to add additional capacitance if the variable capacitor isn't enough, but so far I haven't used an antenna that requires extra capacitance.

One of the shortcomings of this and most other crystal radios is that the tuning dial is not calibrated in frequency, but is simply numbered from 100 to 0. It is doubly difficult to try to set the tuning knob with this radio because the larger the number, the lower the frequency. For example, if the station you want to listen to is at 1600 KHz on the AM dial, the Heathkit must be tuned between 10 and 0, if the station is at 800 KHz, set the dial to 50. What is really ironic is that Heathkit put frequency markers on the station tuning control for the Civil Defense frequencies (640 KHz & 1440 KHz), but they left it up to you to guess where the other frequencies should be. Setting the antenna tuning is equally important and again the numbers are backward. For the highest frequencies, the setting is 0 and for the lowest frequencies, the setting is 100.

The best time of the day to have fun with these kinds of radios

During the daytime and during the summer months, about all that can be received with a little set like this, at least around here, is the trash in English that the local broadcasters pander to and a couple of Mexican language and music stations, but in the evening, electrified layers way up high in the outer fringes of the atmosphere allow radio waves to be bent back down to earth so that interesting stations worth listening to, but which are 200 to 300 (sometimes even more) miles away may be heard loudly and clearly. This long distance "refraction" or bending of the radio waves back to earth (a process called "skip") makes it possible to hear these distant stations, but it isn't like listening to the station next door. This "skipping" of radio waves off electrically charged layers in the upper atmosphere makes these signals subject to all kinds of things including interference from even more distant stations, fading in and out, some strange sounding distortions and sometimes there is even an echo effect. These so-called "propagation effects" can be annoying, but if you just wait a few seconds or minute or so, the signal generally returns.

I think that listening for yourself, to hear what Nature is doing to these signals way up in the sky, is part of what makes listening to the Broadcast Band at night so interesting. There is a certain randomness to this skip that is explained to some degree by solar astronomy and physics. Scientists and engineers all over the world closely monitor our local star and measure it for electrical and magnetic activity. Reports and prediction tables are compiled by various scientific agencies and all this stuff is available on the Internet. When you can test these predictions for yourself by listening for "skip," you are participating in a scientific observation in your own little way.

Listening to far distant stations with a crystal radio like this one shows you how ships like the Titanic could communicate with other ships and to shore stations hundreds of miles away with nothing more than crystal radio receivers. Speaking of the Titanic, two thirds of all the people on her died, but without early radios, very much like this crystal set, everybody would have died. If you make one of these radios and actually put it to use, you will see how, with a good antenna and good sharp tuning circuits, individual radio signals can be picked out from the mass of signals out there and your station can be heard from a long way off under the right conditions. For me, this is a very wonderful thing, especially when I consider that these radios do not amplify their signals, but use the tiny amounts of electrical energy that is picked up by the antenna to make sound. Such is the extreme sensitivity of human hearing and the amazing efficiency of the circuits, the detector crystal and the earphone, that microwatts of power, originally coming from a station hundreds of miles away and landing on my antenna wire, can be heard clearly.

How far we have come

When you think about it, it seems that such basic radio technology represented by this little crystal radio is quite old, but in fact, the first Fleming Valve and crystal radios were invented just a little over 100 years ago. When my mother was a girl, people were building crystal sets so that they could listen to the wonderful new radio broadcasts from the big cities. In a relatively short span of time, the time since my grand parents were young in the 1890s to my parent's time, to this very moment, consider just how far we have come with radio, television, GPS, cell phones, satellite broadcasting, wireless Internet, interplanetary missions to space and so much allied technology.

The End

Having arrived this far, obviously you have a superior attention span and reading ability that far exceeds that of the majority of web users. I highly value the opinion of people such as yourself, so I ask you to briefly tell me:

Did you enjoy this article or were you disappointed?

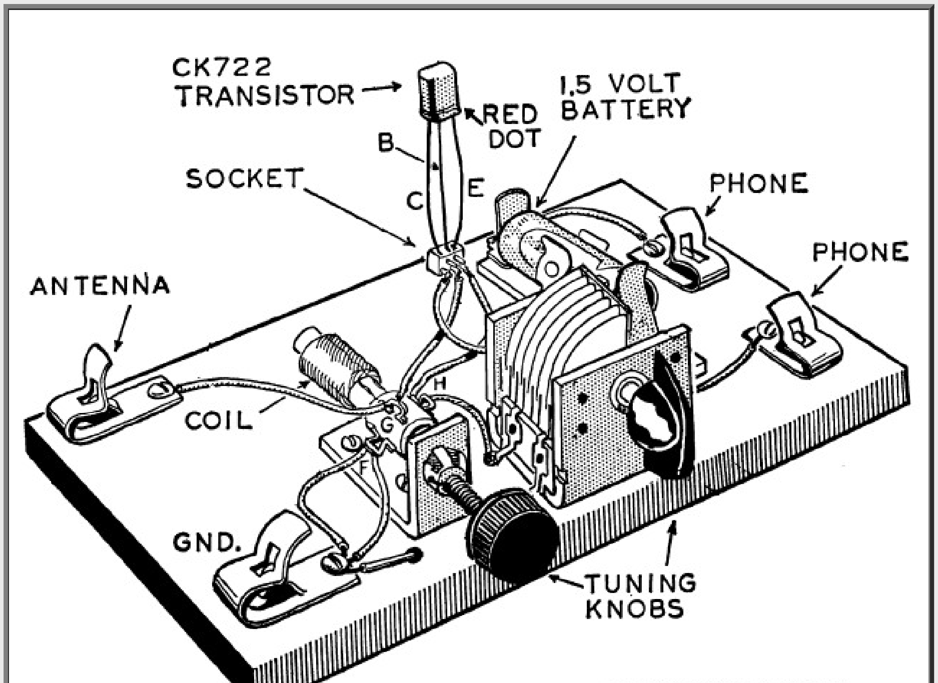
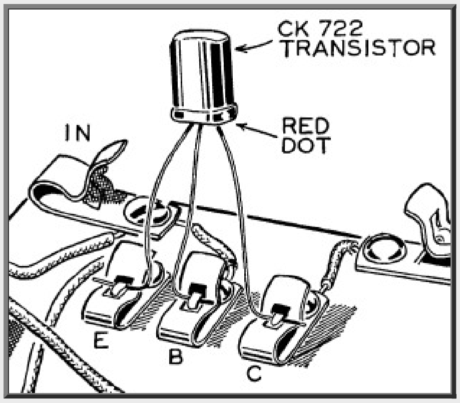
OK, let's put more holes in the base!



RADIO RECEIVER WITH TRANSISTOR DETECTOR

Further on in "The Boys' Third Book of Radio and Electronics" is this receiver. It was off to Ree Electronics for a coil and a transistor. They didn't have a CK722. The CK722 was designed for hobbyists and Ree was an electronics retail and repair outfit. You wouldn't find a CK722 in any piece of consumer electronics. They sold me a Germanium equivalent.

By the way, the CK722 became the most popular transistor in the world, but inside every one was a REJECT from the hearing aid industry. In the early 1950s Raytheon was producing tens of thousands of transistors a month, but only half of them met specifications. If the rejects worked up to a certain point for gain and noise, they were repackaged as a CK722.



I didn't have a socket, so the transistor would be mounted like this. I realized that by adding three Fahnestock clips for the transistor, I wouldn't have to move any of the others. The diode connections could become the battery connections. Antenna, ground and phone connections could all remain the same.

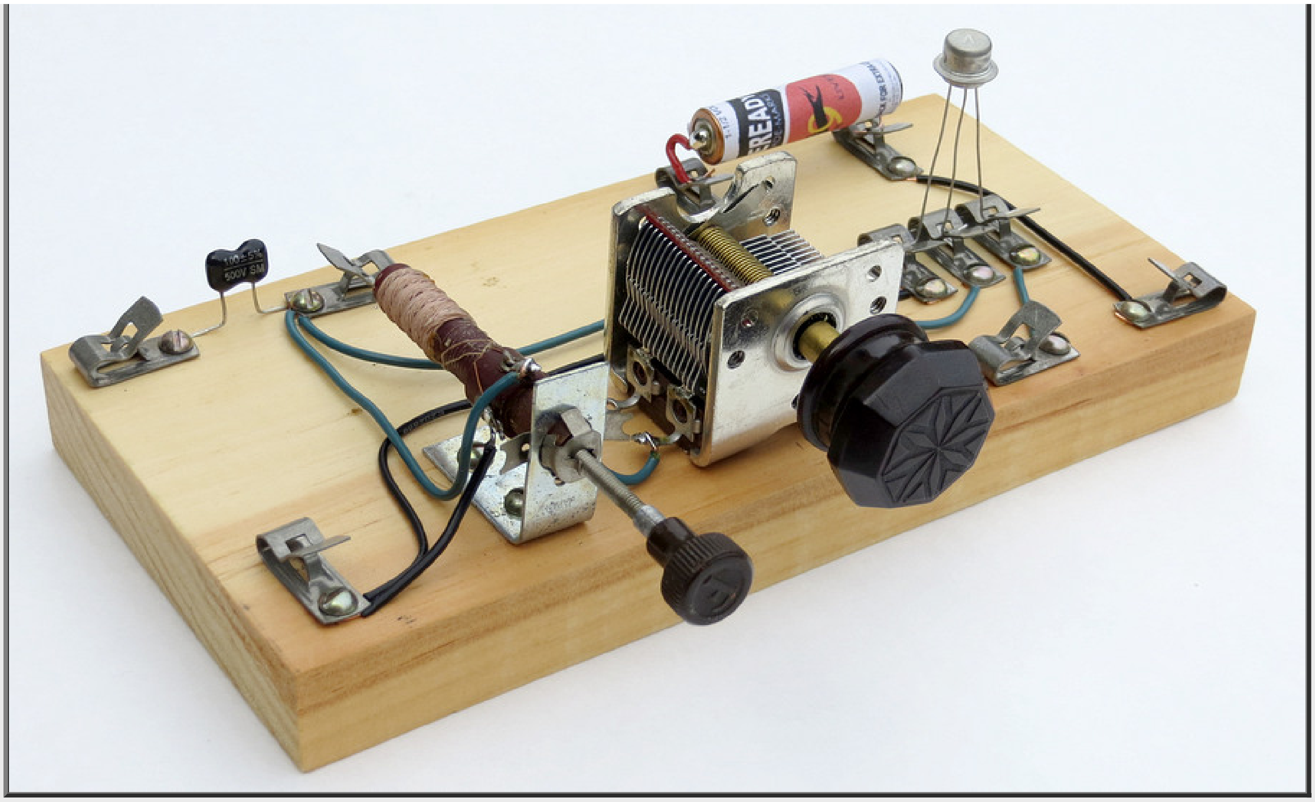
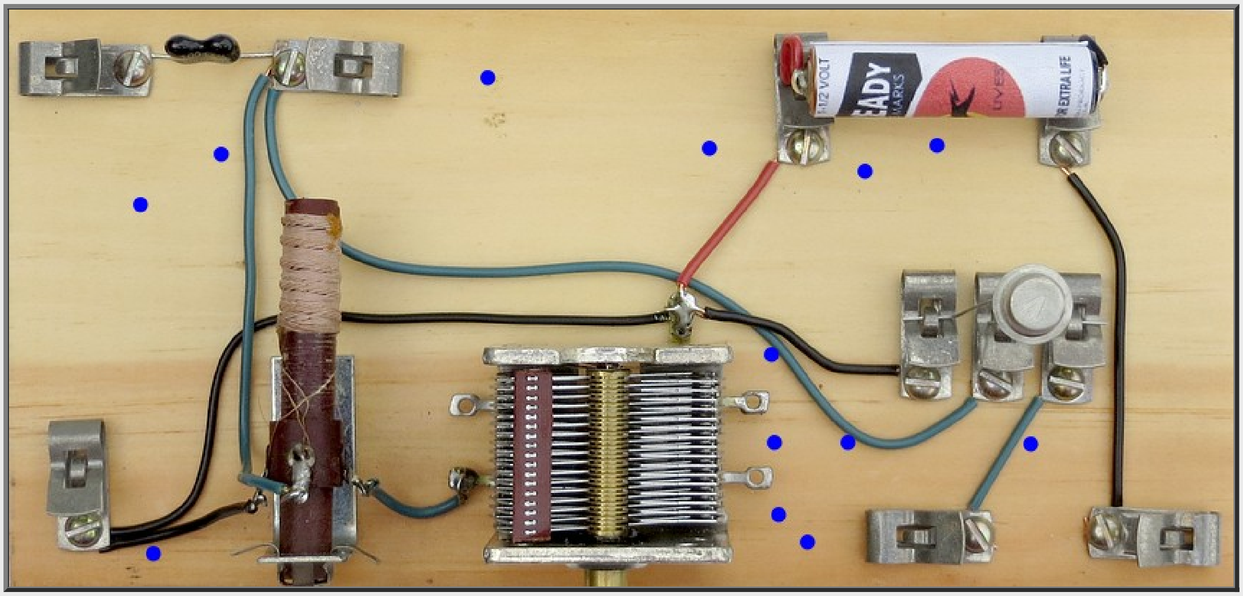
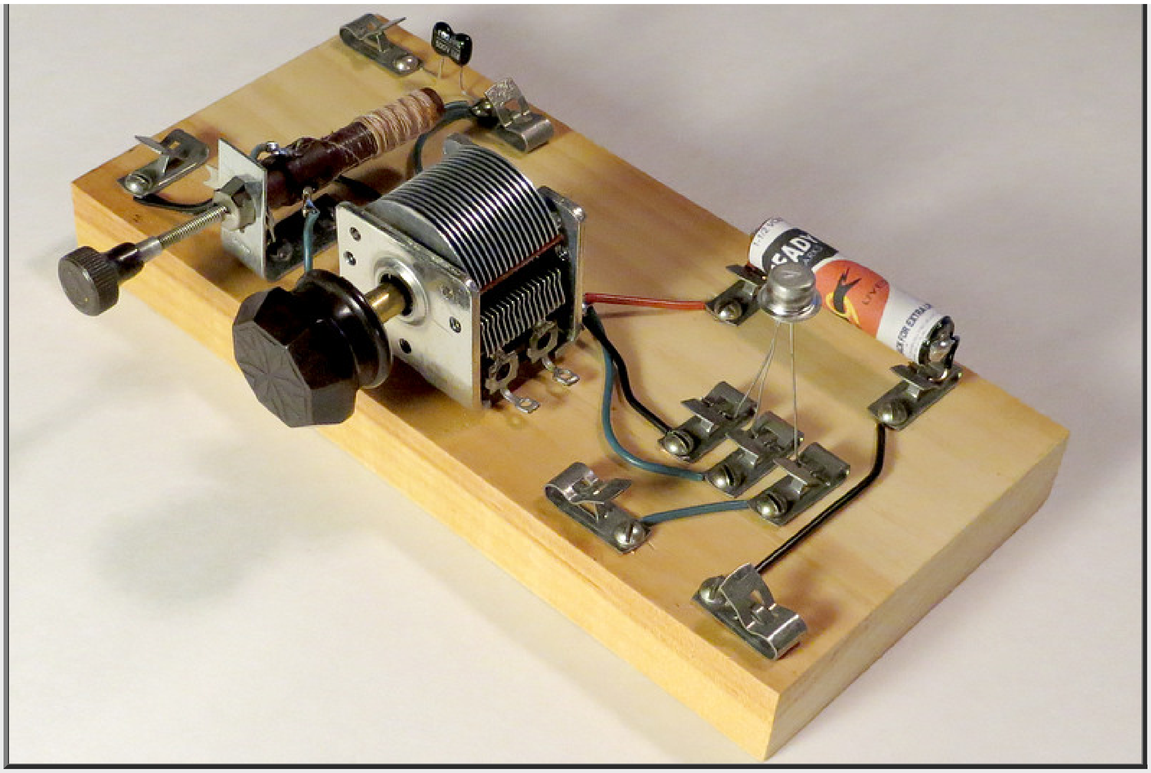
The schematic.



Here is the recreation. The transistor is a CK722 / NTE102 Germanium equivalent. The battery is an AAA skinned with a printed vintage wrapper. I am quite impressed with this. This radio has ONE active component and a battery. The selectivity is very good and our local station, WNPV 1440 AM, came in with plenty of volume.



If this radio works so well, why are there so many other holes in the old base? (Click here) before you read on, so that the violin is playing.



In spite of my efforts in 1966, the radio didn't work. Why didn't it work? I didn't have an actual CK722 transistor, so maybe those guys at Ree Electronics sold me the wrong part. And you probably need that socket. The socket must have something in it that makes the radio work. In other words, I didn't build it EXACTLY like the drawing, so it didn't work.

Also, notice in the drawings that one of the connections going to ground ends in a black dot. I don't know why Morgan drew it this way. I think the wire goes under the base and comes back up behind the variable capacitor. So maybe it didn't work because of that. Maybe the wire had to be under the base for the radio to work.

Actually, there is a MISTAKE in both drawings. The red dot in the top picture is supposed to be on the Collector, not the Emitter. The Base and Emitter connections are swapped in the other drawing. The schematic is correct. I may have fixed the radio by reading the text and looking at the schematic, but I don't remember. It wouldn't have made any difference at the time.

The main reason the radio didn't work was because no current flows through the transistor until you plug in the headphones. The headphones complete the circuit, and are the on/off switch. I didn't have headphones. I had a crystal earplug. The crystal earplug didn't conduct direct current through it, so the set was never "on". It may have worked perfectly but I never knew it.

I could have dropped a 2.2K resistor across the headphone clips, but I didn't know that. My sole source of radio knowledge came from the Alfred P. Morgan books.

So apparently the set was partially dismantled and used for other radio experiments. I still have the transistor I got from Ree Electronics. I plugged it into the set, and it still works. It is so beat up that I didn't use it for the picture.

That music is so sad.

Is that violin music still playing? On the next page are two more crystal sets that didn't work at first.

The Crystal Radio

What's old is new again!

Even a casual auditor of the amateur bands will conclude that the hobby is largely populated by wizened old geezers—and I'm one of them. This is a sad situation because most of us entered Amateur Radio as kids. If ham radio is to continue for generations to come, we must get youngsters interested in radio communication while they're still in grammar school and still capable of wonder. We need to reach them while they are still asking questions about everyday matters (that all too often go unanswered) such as, "Why does it get light in here when I push this thing?"

Reaching today's kids won't be easy. With the Internet, cellular telephones and other forms of global communication commonplace in their lives, the true magic of radio lies buried beneath the technology. We must strip away layers upon layers of complicated hardware and reveal radio in its purest form. The perfect tool to achieve this goal is the "lowly" crystal receiver.

Imagine the curiosity you'll inspire when you demonstrate a radio that has no obvious power source whatsoever! The simple crystal receiver described in this article works surprisingly well. It's selective and produces robust headphone volume. I've been able to tune several local AM broadcast stations with ease. Best of all, it's inexpensive, uses readily available parts, and can be built by a youngster (with a little guidance). Of course, adults will love this little receiver, too.

There is a fascinating resurgence of interest in crystal radios. Even hams normally accustomed to owning rigs with four-digit price tags are rediscovering the joys of simple, "powerless" reception. To get a taste of what is going on, pick up a copy of *Crystal Set Projects* from the Xtal Set Society, Box 3026, St Louis, MO 63130; tel 314-725-1172, or visit their Web site at **http://www.midnightscience.com**. (The book was reviewed in the August, 1997 *QST*, page 102.)

About the Circuit

The circuit shown in Figure 1 was developed in the early '30s by Elmer G. Osterhoudt. Selectivity problems plagued most crystal sets of the day due to the proliferation of broadcast stations. Elmer devised a solution. He determined that poor crystal receiver selectivity was caused by the headphones swamping the tuned circuit and lowering its Q. The net result was an inability to separate individual signals. Elmer improved selectivity considerably by connecting the detector near the cold (ground) end of the tuned circuit to minimize the swamping.

Capacitor C2 is used to match the antenna system, and C3 is the main tuning capacitor. Absent from this circuit is the finicky galena-and-catwisker detector. It has been supplanted by a 1N34 germanium diode that is connected near the grounded end of the tuned circuit that includes coil L1. C1 is an RF bypass capacitor.

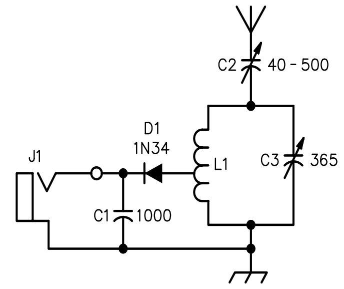

Figure 1—Schematic diagram of the crystal receiver. Parts are available from Radio Shack or Antique Electronic Supply (6221 South Maple Ave, Tempe, AZ 85283; tel 602-820-5411) as noted.

C1—1000 pF mica or disc ceramic trimmer (Radio Shack 272-123)
C2—40 to 500 pF trimmer capacitor (Antique Electronic Supply CV-263)
C3—365 pF variable capacitor (Antique Electronic Supply CV-231)
D1—1N34 germanium diode (Radio Shack 276-1123)
J1—$^{1}/_{4}$-inch, 2-conductor headphone jack (Radio Shack 274-252)

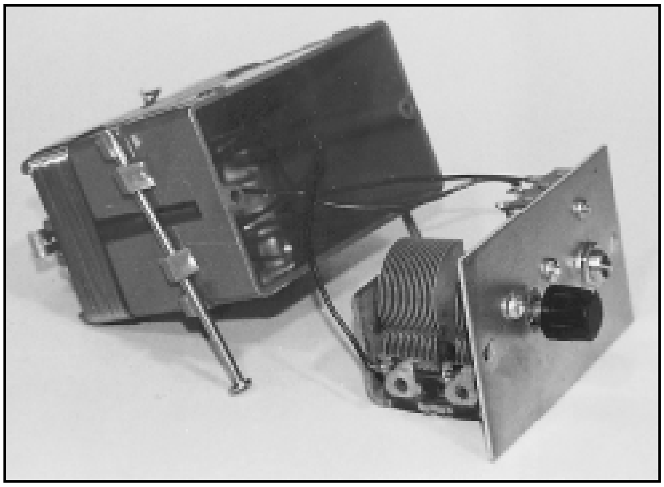
Fahnestock clips (Antique Electronic Supply SH-11-4034)
2000-Ω headphones (Antique Electronic Supply PA-466)

Headphones

You must use high-impedance headphones (2000 Ω or greater) with crystal receivers. If you attempt to use common 8-Ω headphones, you'll have very disappointing results. You'll find high-impedance headphones at hamfest flea markets, but if you're not up to the hunt, you can buy them from Antique Electronic Supply (see Figure 1).

The Importance of a Good Antenna System

Since the crystal receiver depends completely on the energy from the transmitted signal, you need to gather as much signal out of the air as possible! Remember that this receiver is designed to tune the AM broadcast band. A half-wavelength dipole cut for about 1 MHz would be ideal, but few of us own enough real estate to accommodate a 500-foot long antenna. The practical solution is



Plastic electrical outlet boxes make terrific enclosures. Note that I've mounted the main tuning capacitor, C3, and the headphone jack on the front using copper-clad PC board.

to simply use an end-fed wire about 100 feet in length. You'll also need to provide a connection to an Earth ground (a cold-water pipe may suffice). With the proper antenna system, you should be able to receive most of the AM stations in your area. If you live in a rural location without an AM broadcaster nearby (within about 50 miles), try using even more antenna wire. Just string it over trees, bushes, or any other supports.

Construction

You can build a crystal receiver into almost anything. I used plastic electrical outlet boxes. They're available at home centers and hardware stores. They are attractive, rugged and inexpensive. They even serve as forms for winding the coil. I made the front panel of my box from a piece of copper-clad PC board. You can cut this material into the proper shape using a hacksaw, and it is easily drilled for mounting parts.

For C3, a miniature variable capacitor salvaged from an old AM-only radio will work, but a single-section air variable is better. If you don't have these capacitors in your junk box, don't despair. You can order one from Antique Electronic Supply.

L1 is wound on the outside rear portion of the enclosure and consists of 32 turns of 22-gauge enamel-covered wire. The coil is tapped nine turns from the grounded end. The tap is made by tightly twisting about 1 inch of the magnet wire and scraping off the enamel insulation. You can secure the windings to the enclosure with transparent plastic tape.

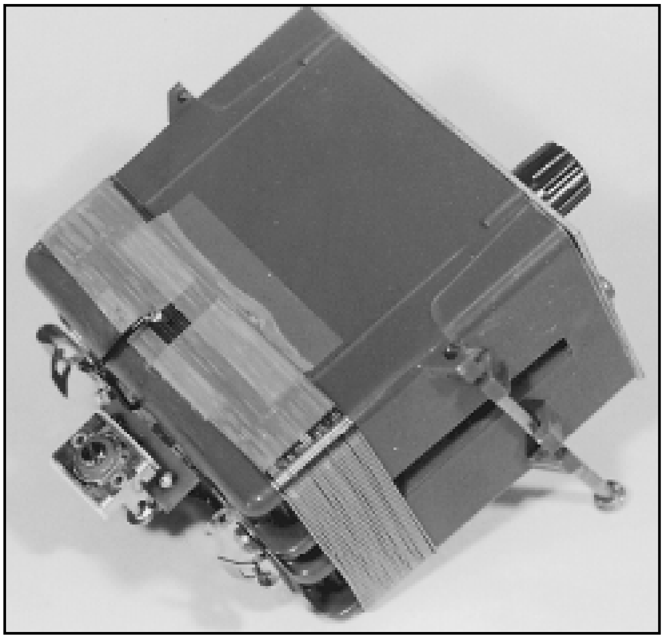
The antenna trimmer capacitor (C1) and the Fahnestock clips for the antenna and ground connections are mounted on the rear of the enclosure. The tuning capacitor, phone jack and detector are mounted on the front panel. Interconnecting wires are fed through holes in the enclosure and soldered to the trimmer capacitor, ground and cold connections.

Operating Adjustments

Connect the antenna, ground and headphones. Tighten the antenna trimmer capacitor C2. Slowly adjust C3 to tune in the stations. Note the number of stations and log their call letters and frequencies. Readjust C1 to provide the best trade-off between volume and selectivity. If you're using your crystal radio near a particularly strong broadcast station, removing the ground connections will often improve selectivity (with some reduction in volume).

Use Your Radio as a Teaching Tool!

You can use your crystal radio to teach a number of important concepts. For example:



The rear view of the crystal radio enclosure. You can easily see the windings of coil L1 held in place with transparent tape.

Inductance: Applying the "right hand rule," the coil for the tuned circuit can be used to explain how a magnetic field is developed by electron flow through a conductor, and how the magnetic field is increased by forming the conductor into a coil.

Capacitance: Varying capacitance may be illustrated by simply observing how the total area increases as the rotor plates mesh with the stator plates. The compression trimmer capacitor (C1) illustrates the function of a dielectric other than air. It also shows how the capacitance can be varied by changing the separation between the plates.

Resonance, modulation and detection: You can teach these concepts by inviting your student to tune in a station while you display the modulated RF on an oscilloscope! Move the 'scope probe from one side of diode D1 to the other to illustrate "before" and "after."

Magnetism and transduction: High-impedance headphones are ideal instructional aids to demonstrate these ideas. Disassemble a pair of headphones and show your students what's inside. Touch the permanent magnet with a screwdriver so they can see that it is indeed magnetic. Explain how the detected signal flows through the tiny headphone coil, creating a magnetic field that adds or subtracts from the field produced by the permanent magnet. This causes the metal diaphragm to vibrate, creating sound! What began as electrical energy has become mechanical energy—*transduction*.

Summary

Throughout the years, the simple crystal radio has spawned tens of thousands of radio amateurs, engineers and electronic hobbyists. And despite the antiquity of its design, it is still an effective tool for recruitment and instruction. A crystal radio is a delightful device, and the perfect way to introduce the wonder of radio to a young mind—or rekindle it in your own!

CRYSTAL SET CONSTRUCTION

SIMPLE INSTRUCTIONS FOR MAKING NINE CRYSTAL SETS

by B. B. BABANI

There is to-day a marked revival of interest in crystal receivers, and this book has been specially prepared to introduce the home constructor to the design and building of the various types. The text is simple and free from technicalities, so that even the young reader may confidently embark on the construction of any of the receivers shown.

FIG. I SYMBOLS USED IN THE CIRCUITS DESCRIBED.

1. Aerials.

One of the essentials for satisfactory reception with crystal sets is an efficient aerial. Four different types are suggested and are shown in Fig. 2.

There are several important points to be noted when erecting an aerial for a crystal set.

(1) See that it is suspended as high as possible and is not screened by tall buildings, obstructions, etc.

(2) The aerial itself and the lead-in from the aerial must be adequately insulated. Be sure that the porcelain or plastic insulators do not permit the aerial or lead-in to touch the building, tree, or post from which they are suspended. The lead-in should be brought into the house through an insulated rod.

(3) It is exceedingly important to use insulated copper wire, either single or multi-stranded, for both the aerial and the lead-in.

2. Earths.

An adequate and efficient earth contributes to the good performance of any well-designed crystal set and Fig. 3 shows the best method of obtaining an efficient earth where there is a garden or patch of ground available at a short distance from the receiver.

Obtain a 3-ft. length of ½-in. galvanised iron pipe and at one end drill a hole right through. Insert a bolt with spring washer and locking nut in the hole. Connect the earth lead-in wire to the bolt; the other end of the lead-in to the earth connection on the receiver. Leave both ends of the pipe open. Insert the end opposite the bolt into the ground vertically until only 3-in. are showing above the surface of the surrounding earth.

It is important to see that the surrounding ground is kept damp, if necessary by occasionally pouring a pint or two of water down the open projecting end of the pipe.

Ready-made copper earthing rods with a pointed end for easy hammering into the earth are sometimes obtainable from radio dealers.

Should a garden not be available, an alternative earth is a cold water pipe coming from a rising main. Simply file very lightly the pipe at the back of the tap and wind the copper wire earth lead-in round the filed part and cover the joint with insulating tape.

In no circumstances should a gas pipe be used for an earth.

3. Crystal Detectors.

Most radio dealers can supply very efficient permanent or semi-permanent crystal detectors of proprietary makes. However, there are always available quite a number of ex-Government surplus units which are called crystal valves and, though these were originally designed for a very different use in service equipment, they are easily adaptable and will give extremely efficient results when used in circuits designed for them. To enable the constructor to purchase suitable types for this purpose—and they cost very little—the following list gives the Government reference numbers.

CV 101, CV 102, CV 103, CV 111, CV 112, CV 113, CV 226, CV 241, CV 246, CV 247, CV 253, CV 291, CV 351, CV 361, CV 364, CV 367, CV 727, CV 749, and CV 1785.

One of the satisfactory proprietary makes of this class of crystal detector is the BTH CS7A, which, incidentally, is the commercial equivalent of the CV 253.

For all these Government types, one connection should be made to each end by arranging a holder to fix them into or by carefully soldering the appropriate connecting wires to each end.

FIG.2 AERIAL SYSTEMS

4. Coils.

In Fig. 3 two methods are shown of fixing the coil to the chassis. However, the ingenious constructor may evolve another arrangement.

The important thing to remember is that the coil should be fixed so that it is completely insulated from the metal chassis that may be used.

It is also important to remember that if a metal chassis is used, one must see that all components and wiring, with the exception of earth connections, are adequately insulated from this chassis so as to make sure that no short circuits take place. It is recommended that all crystal sets should be built on a panel, and that both panel and chassis should be of bakelite, paxolin or perspex, as these three materials are efficient insulators in themselves.

5. The Beginners' Crystal Receiver.

The popularity of the crystal receiver among beginners is undoubtedly due to the very modest outlay necessary, and the ease with which such receivers may be built. It is not always appreciated that, to obtain worth while results,

far more care in avoiding losses is necessary than with a three or four valve receiver. One reason for this is the fact that the crystal receiver can offer no help by way of amplification and it is therefore dependent on an efficient aerial/earth system, low loss design within the receiver itself, and the use of sensitive headphones. The experience gained is well worth the time expended since, when more ambitious receivers are attempted, the constructor will remember the benefits gained by efficient construction and installation with the result that each receiver attempted will be an instrument capable of giving a first class performance.

Losses within the receiver itself may be considerably reduced by efficient coil design. Unfortunately, selectivity is a factor which must not be overlooked; it is this factor which governs the sharpness of the tuning and permits the separation of adjacent powerful stations. The greater the selectivity, the greater the ease with which signals may be separated; but at maximum selectivity the received signals are at minimum strength. In Fig. 4, the coil is tapped at four points, which enables the best point between selectivity and sensitivity to be chosen. The nearer the aerial tap to the earth end of the coil, the greater the selectivity. The pre-set condenser C1 also aids selectivity; at minimum capacity the selectivity is high, and *vice versa.*

Used in conjunction with the coil taps, the constructor should have no difficulty in selecting a condenser setting and tapping point which permit the reception of strong signals and at the same time effect the required separation of powerful stations.

The coil is constructed on a former 3-in. diameter × 2-in., and consists of 50 turns 36 S.W.G. enamelled wire close wound and tapped at every tenth turn. These taps are brought out in the form of loops twisted firmly so that there is no actual break in the winding continuity. After completion the winding may be painted with Durafix to prevent any movement, and the taps and two free ends cleaned with emery cloth to remove the enamel. The layout and wiring is shown in Fig. 4. The headphones should have a resistance of some 4,000 ohms or more and should be of reputable manufacture. Any of the aerials previously described are suitable for use with this receiver.

1 Coil former 3-in. dia. × 2-in.
1 Ebonite or Bakelite panel 6-in. × 5-in. × ⅛-in.
4 terminals, connecting wire, etc.

6. Frame Aerial Receiver for Local Station use on Medium wave bands.

This receiver was specially designed for constructors who are within 5 to 10 miles of a powerful station and who have no facilities for constructing a good outdoor aerial.

The frame itself consists of two ¾-in. × ¾-in. square section wooden rods each 36-in. in length. These are placed together at their centre line to form a cross; they are fastened by a nut and bolt and these in turn pass through an upright piece of wood ½-in. × 1-in. section 2-ft. in length. This upright support is then screwed into a baseboard 8-in. × 8-in. × 1-in. thick. At each of the arms of the 36-in. cross a 4-in. strip of ½-in. square section wood is placed. Reference to Fig. 5B will give the details of the construction of this aerial quite clearly.

It will be noted that approximately 85-ft. of 20 S.W.G. double cotton-covered wire are required for the inductance to cover the medium wave broadcast band. The wire should be wound around the four crossbars, thereby creating

a square wire frame, and each turn of the wire should be spaced approximately ⅛-in. The best way to effect this spacing accurately is to file on the 4-in. crossbars a number of small nicks at ⅛-in. intervals. The two ends of the wire should then be brought down on the two terminals which may be screwed into the square baseboard and two leads taken from there to the crystal set itself.

The actual set may be constructed on a small ebonite, paxolin or perspex panel 8-in. × 5-in. which may be screwed to one side of this base supporting piece of wood, thereby making the set virtually self-contained except for the earphones. Fig. 5A shows the circuit of the receiver.

To obtain the best results with this receiver, the aerial should be rotated by hand until the signals become loudest.

C1 1 .0005 mfd. variable condenser.
C2 1 .0005 mfd. fixed condenser.
1 condenser dial marked 0 to 100 or 0 to 180.
1 pair of high sensitivity earphones.
85-ft. to 90-ft. of 20 S.W.G. double cotton covered wire. (8oz.)
Sufficient connecting wire for wiring purposes.

7. Long Distance Receiver.

This receiver has been specially designed to achieve high sensitivity. With a sufficiently good outdoor aerial effective reception has been obtained up to 150 miles.

The circuit is quite straightforward, as can be seen from Fig. 6 and the only special point is in winding the coil L1.

This coil consists of a 2½-in. diameter former on which are wound a total of 51 turns using 24 S.W.G. double cotton wire. Starting at one end, tap every two turns until there are eight taps; wind a further 15 turns and tap; then a further 10 turns and tap; finally, add 10 turns to end the winding. The wire should be close wound, *i.e.*, with turns touching.

To obtain the best results, the two crocodile clips A and B should be tried on the various coil taps until the loudest reception is obtained. It may be found in use that the loudest reception of any particular station causes another station to be heard at the same time; care should, therefore, be taken to select the appropriate tapping point to separate any two powerful stations that may interfere with one another.

4 oz. 24 S.W.G. DCC copper wire.
Coil former 2½-in. dia. × 3-in.

2 Condenser dials marked from 0 to 100 or 0 to 180.
1 Permanent crystal detector.
C3 .001 fixed condenser.
1 pair of high sensitivity earphones (preferably between 4,000 ohms and 8,000 ohms impedance).
2 Crocodile clips.

8. High Gain Receiver.

This receiver has been designed to give good reception up to 50 miles distance from any normal power broadcasting station in the medium band. It is a very selective circuit and will therefore enable the user to separate closely situated stations.

It will be noticed in the circuit (Fig. 7) that the variable condenser C1, has an on/off switch S1 to throw it out of circuit if necessary. It is used to increase the selectivity of the receiver and, in operating, it should be tried with this condenser either in or out of circuit on the various tappings on the coil L1.

L1 consists of 90 turns of 22 S.W.G. double cotton covered wire wound on a 2-in. diameter former and tapped every ten turns. L2 separately wound on a 2-in. former, consists of 90 turns of 22 S.W.G. double cotton covered wire, also tapped as L1. The components required are given on page [illegible]

2 Dials for variable condenser marked 0 to 100 or 0 to 180.

9. High Selectivity Receiver.

This circuit (see Fig. 8) is for use in high saturation strength areas where it is desired to separate powerful stations. The circuit is not complicated and is extremely effective.

It will be noted that C1 and C2, each .00035 mfd. capacity, are 2 gang unit.

The only special point in this set is the design of coils L1, 2 and 3, which are constructed as follows: L1, 60 turns of 22 S.W.G. double cotton covered wire on a 3 × 4 inches former tapped every five turns; L2, 15 turns of 22 S.W.G. double cotton covered wire on a 3 × 6 former; and L3, 85 turns of 22 S.W.G. double cotton covered wire wound on the same former as L2, the two windings being separated by approximately ¼-in. (see Fig. 8).

Note that the aerial lead is brought down to one of the tappings on wire L1. This should be tried on each of the tappings and the one giving the required selectivity should be used.

C1-2 2-gang variable condenser .00035 mfd.
2 3-in. formers for coils L1-2-3.
8 oz. 22 S.W.G. DCC.
C3 .0005 fixed condenser.
1 Semi-permanent crystal detector.

10. Battery-aided Crystal Receiver.

Fig. 9 shows a design which utilises a 9-volt grid bias battery to improve performance.

The charge built up in the .02 mfd. fixed condenser is changed to a positive current when it passes through the coil L1. This, in turn, is superimposed on the positive charge that is commencing to be rectified by the crystal detector and thereby increases the signal strength.

Coil L1 consists of a 4-in. diameter former wound with 85 turns of 24 S.W.G. double cotton covered wire tapped at 5, 25, 45 and 65 turns from the earth end. The earth end and these four taps are brought out to five small sockets and the connection from the earth is taken to a small socket. The plug should be tried in each of the five positions to find which one gives the greatest signal strength.

The 9-volt battery is connected across the .02 mfd. condenser and special care should be taken to see that the battery is connected correctly, *i.e.*, negative pole to earth.

C3 Fixed condenser .02 mfd.
1 pair of high sensitivity headphones.
1 Clix plug.
5 Clix sockets.
1 9-volt grid bias battery.

11. Medium and Long wave band Receiver.

This set has been designed for reception on two wave bands.

Care must be taken in winding the coils L1, 2, 3 and 4. These are wound on a single 3-in. diameter former. L1 consists of 30 turns of 28 S.W.G. DCC tapped at 8, 16 and 24 turns. L2, 60 turns of 32 S.W.G. DCC. L3, 40 turns of 28 S.W.G. DCC, and L4, 80 turns of 32 S.W.G. DCC. All are close wound and are separated from each other as follows: between L1 and L2, 3/16-in.;

1 Pair of high sensitivity earphones.
1 3-in. dia. × 8-in. former.
2oz of both 28 and 32 S.W.G. double cotton covered wire to make these 4 coils.
1 Permanent crystal detector.

In use, the plug should be tried in each of the three sockets to find the point which gives the best results. The switch is used as a wave band change switch.

12. Ultra Sensitive All Wave Receiver.

The receiver shown in Fig. 11 is for long distance reception. It is a novel circuit and, though apparently complicated in construction, it is really very simple to assemble with the minimum of tools and labour.

It will be seen from the circuit diagram that there are two banks of sockets, five black and six red. When using this set the appropriate black and red plugs should be inserted in whichever of the similar coloured sockets give the best results. The coil is quite easy to construct and consists of a primary winding which is inserted at the earth end of the secondary winding. For the medium wave band, the secondary winding L2 consists of 54 turns of 20 S.W.G. enamelled or cotton covered wire. This coil has four taps in addition to the starting point and the end connection, and these taps are taken at six turns, 14 turns, 27 turns and 40 turns from the earth end. The taps are taken out and a connection is made to an appropriate socket, as shown in the diagram.

The coil is wound on a 3-in. diameter former which may be a paper tube, bakelite, paxolin or perspex, and spacing is approximately 17 turns to the inch.

For short wave work down to about 30 metres, L2, the secondary coil, will consist of the same diameter former wound with 15 turns of the same gauge wire, the four taps being taken at 3, 6, 9 and 12 turns from the earth end.

L1, the primary coil, is used for both wave bands and consists of 11 turns of similar gauge wire to that used for L2, wound on a 2-in. × 1-in. former, the winding to be spaced the same as L2. The coil is then inserted at the earth end of whichever secondary coil L2 is being used.

The crystal detector may be one of the semi-permanent types freely available to-day; the old-fashioned cat's whisker pattern; or one of the silicon permanent detectors which are sold by many surplus dealers.

The 'phones should be of a standard type 4,000 ohms impedance although 'phones of other values will probably operate quite satisfactorily with this powerful receiver. It should, however, be stressed that the better the headhones used, the more satisfactory the reception.

Coils for other wave bands may be experimentally designed by the constructor, remembering that four tappings are advisable for the secondary coil L2.

A long aerial is very desirable with this receiver, placed as high as possible. It is recommended that a minimum length of 70-ft. be allowed, to include the aerial and lead-in.

The values of the components are shown in the following components list. The constructor should experience no difficulty in obtaining excellent results from this cleverly designed receiver.

C1 .0005 variable condenser.
C2 .002 fixed condenser.
1 semi-permanent crystal detector.
1 coil former 3-in. dia. × 4½-in.

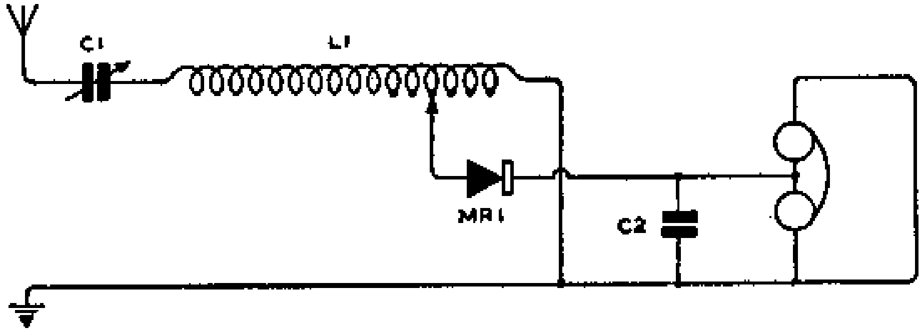

FIG. 12 ADVANCED CRYSTAL DIODE RECEIVER

13. An Advanced Crystal Diode Receiver.

The modern crystal diode of the radar type does not require any adjustment and thus has a distinct advantage over the ordinary crystal detector which needs delicate adjustment—even the semi-permanent type.

Such crystals are now obtainable on both the regular and the surplus markets, and a popular type is the B.T.H. CS7A silicon crystal (also coded as CV 253).

A rather different circuit from the usual crystal set arrangement is needed to suit the characteristics of a crystal diode. The diode must be tapped on to the tuning coil, and it is found that the tuning circuit itself gives best results if a series-tuned acceptor circuit is used. The circuit of a radar crystal receiver is shown in Fig. 12. The type of aerial used with this circuit has a very great bearing on the behaviour of the receiver for, in effect, the tuned circuit, with a series resistance equivalent to the reflected crystal load resistance, is in series with the capacitance of the aerial to earth and the aerial's effective series resistance.

At resonance—when the combination is tuned to any particular signal—the inductance resonates with the capacitances of the tuning condenser and the aerial in series, and the final effect is that the reflected load of the crystal, in series with the coil's R.F. resistance, is paralleled across the aerial's series resistance.

For maximum power transfer, the crystal load resistance must be made equal to the sum of the aerial series resistance and the coil R.F. resistance, and so the method in which the crystal is tapped into the tuning coil, and the exact capacitance required to tune the receiver to any required signal, must depend to a very great extent on the aerial itself.

At the same time the crystal resistance varies with the signal strength, the resistance being high for weak signals and dropping by as much as 50 per cent. and more for strong signals, so that this effect also has a bearing on the correct coil tap. The output impedance of the crystal also varies similarly, affecting the matching of the headphones into the crystal diode, and so for any set of conditions, the receiver requires to be matched up to both the aerial and the signal being received for best results. This would mean a series of coil taps and (theoretically, not practically) a matching transformer between the diode and the headphones; but in practice it will be found that a receiver using standard parts can be built up to give very good results under various conditions.

It has been shown already that the tuning of the receiver depends to a great extent on the characteristics of the aerial, and while a .0005 mfd. variable capacitor is shown in Fig. 12 as the tuner, the constructor must be prepared to experiment with different capacitance values until the required station is tuned in. The range of reception given by the receiver is quite good, if a really long and high aerial, and a good earth connection, are used; but no more than the local station signal can be expected, and the tuning therefore must be adjusted to suit the station frequency.

It must be mentioned that the headphones are shown parallel connected. High resistance headphones of the 4,000 ohm type must be used, and if two of these are connected in parallel rather than in the more usual series method, they will provide a roughly accurate match to the crystal. If more than one pair of headphones are to be connected in, then the pairs of headphones may be left series connected in the usual manner, the sets of headphones being connected in parallel.

The capacitor across the headphone terminals completes the crystal R.F. circuit, and any value between about 0.001 and 0.005 mfd. will serve. The higher capacitance will, of course, by-pass some of the higher audio frequencies, so that if good steady reception is obtained some experiment with this condenser is also worth while.

C1, .0005 mfd. variable condenser.
C2, .005 mfd. fixed condenser.
M.R.1 CV 253 Crystal diode.
Coil former 1½-in. dia. × 4½-in.
4oz. 26 S.W.G. enamelled copper wire.

Coil details are as follows: 150 turns of 26 S.W.G. tapped at 20, 25, 30, 35, 40 and 45 turns from the earth end. At each tapping-point the wire should be twisted up into a loop and the winding then continued without breaking the wire; when the coil is completed and the ends anchored the tapping loops can be bared.

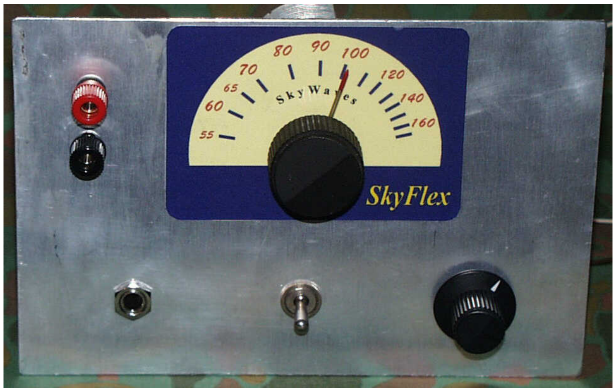
12-volt 1-tube Regenerative Receiver:

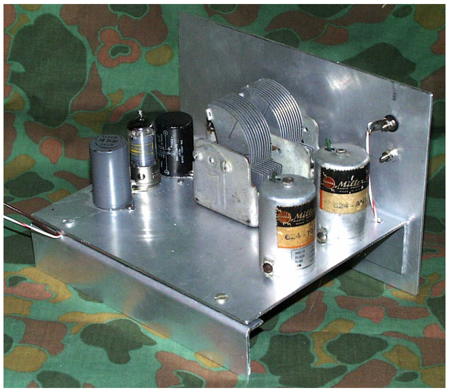
This article first appeared in the Delaware Valley Historic Radio Club's *Oscillator*.

12-volt 1-tube Reflex Receiver:

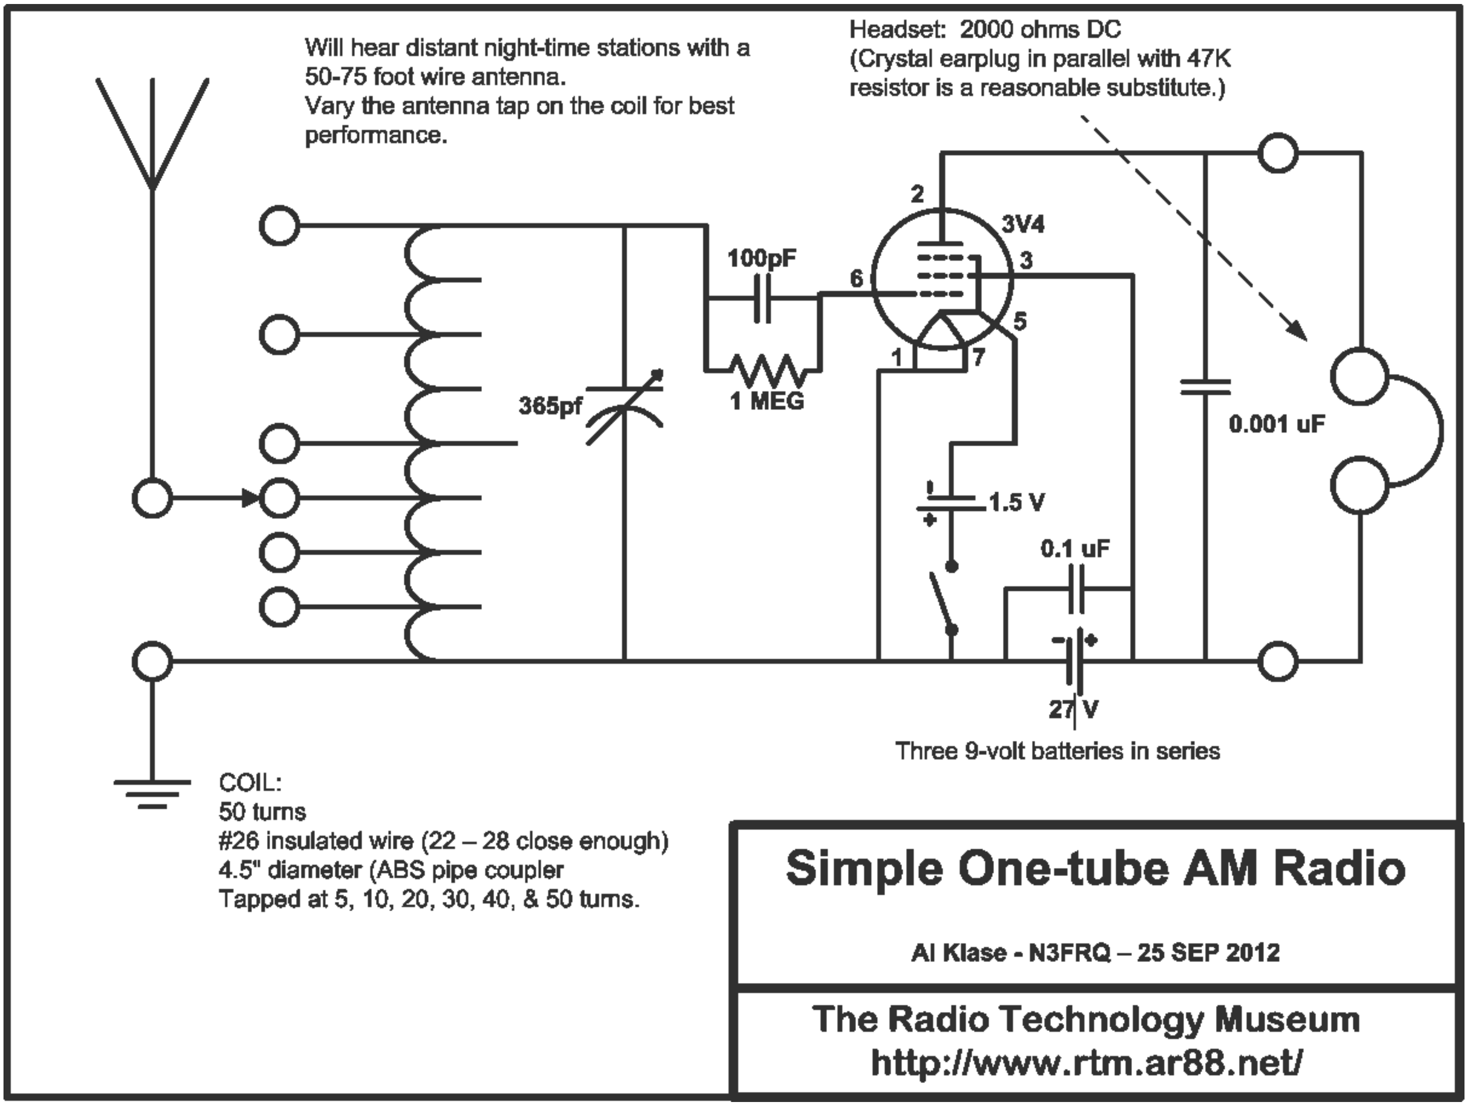
I was so encouraged by the success of the simple regenerative set that I undertook the design of a much more elaborate one-tube set using a "reflex" circuit. In this receiver the signal passes through the tube twice: first, as radio frequencies and then a second time, as audio. Because there is considerable RF gain before the detector, this radio is far more sensitive than a simple regenerative set.

This is not a project for beginners. The design employs a lot of hard-to-get and potentially expensive parts, almost enough to build a rudimentary superheterodyne. You'll probably need a sweep generator to get the tunable band-pass filter working correctly. You should be prepared to reengineer the circuit to suit the parts on hand.





Simple battery tube radio based on the PGXS crystal set.



Will hear distant night-time stations with a 50-75 foot wire antenna.
Vary the antenna tap on the coil for best performance.

Headset: 2000 ohms DC
(Crystal earplug in parallel with 47K resistor is a reasonable substitute.)

Three 9-volt batteries in series

COIL:
50 turns
#26 insulated wire (22 – 28 close enough)
4.5" diameter (ABS pipe coupler
Tapped at 5, 10, 20, 30, 40, & 50 turns.

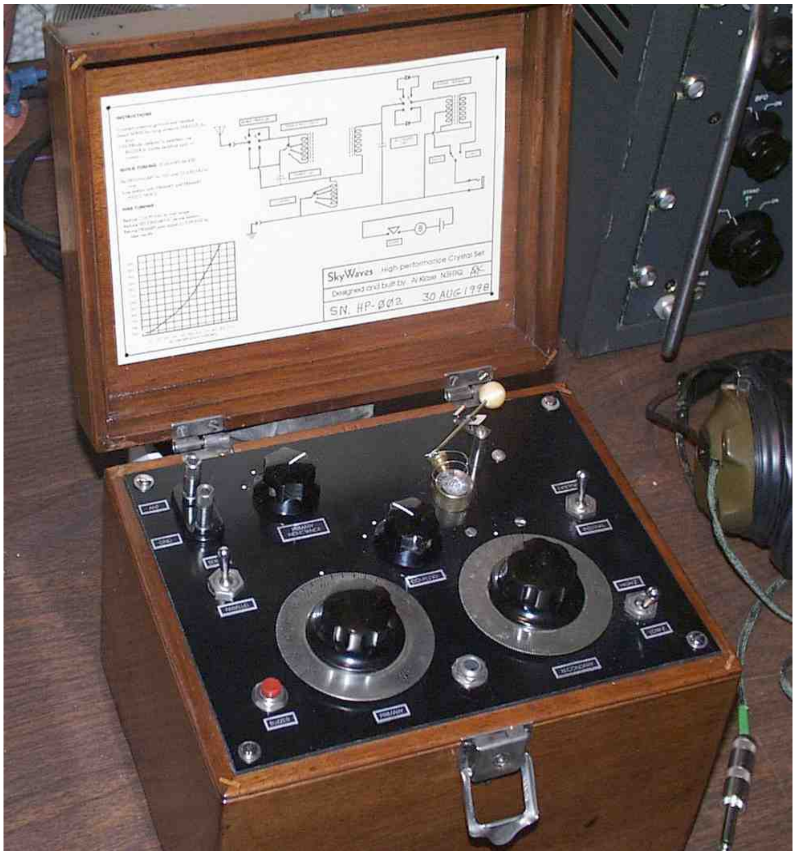
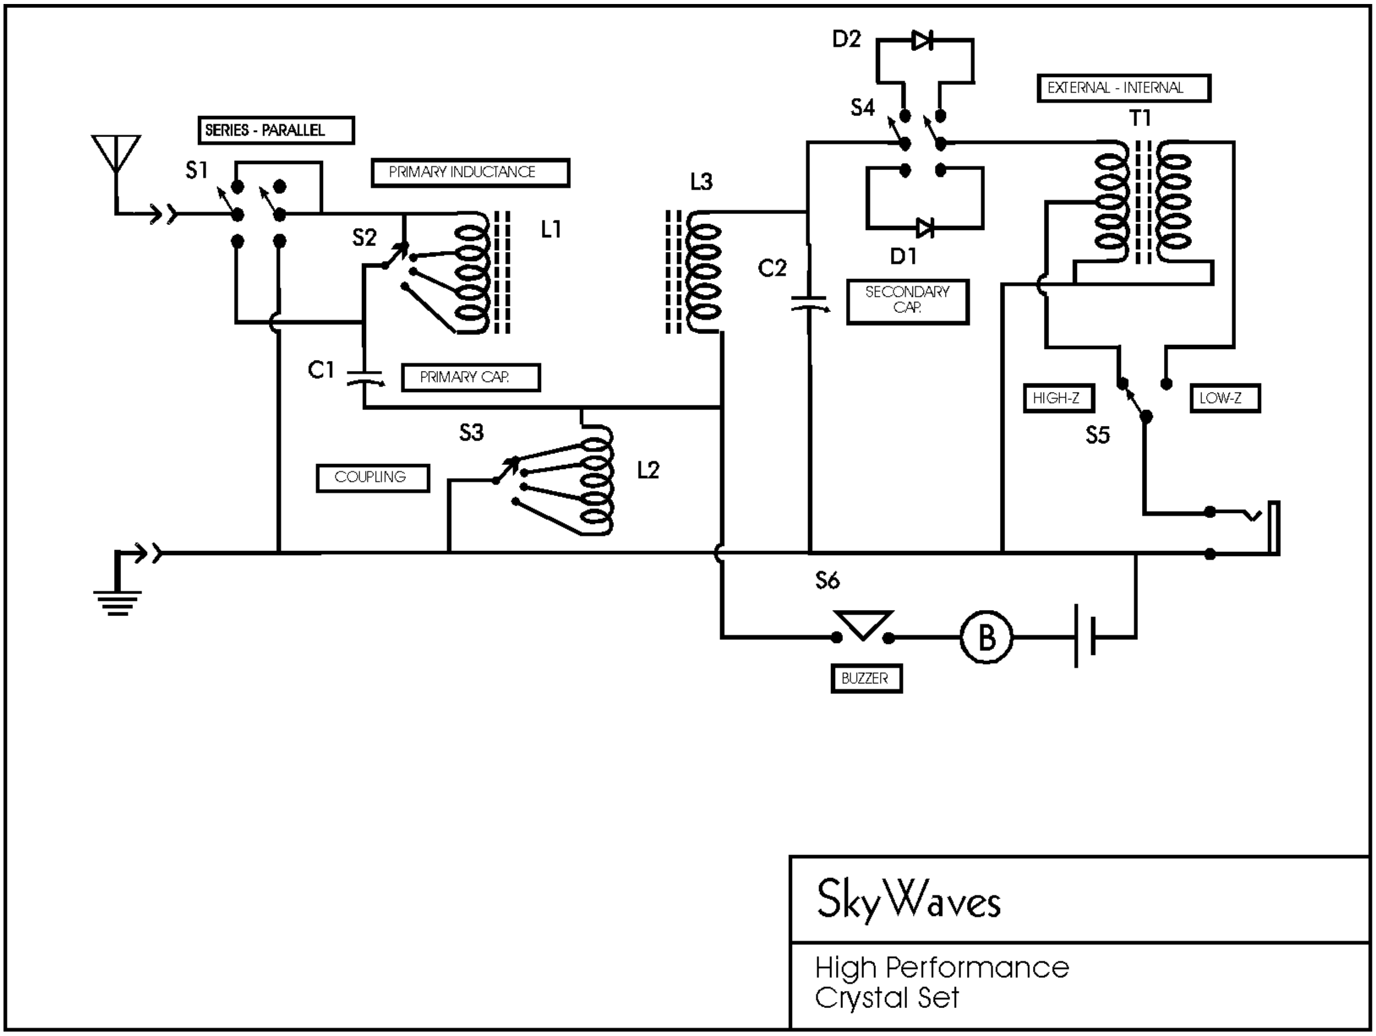
THE SKYWAVES HIGH-PERFORMANCE CRYSTAL SET

Copyright 1999 - Alan R. Klase - All rights reserved



This radio is the result of approximately ten years of sporadic research and experimentation with crystal sets from an engineering perspective. Serious professional development of passive receivers virtually ended with the introduction of reliable vacuum tubes. My conclusions are really pretty straight forward: One needs to pay attention to proper impedance matching at each point in the circuit to assure maximum signal transfer. Multiple tuned circuits with variable coupling allow the operator to trade sensitivity for selectivity. Lastly, a high performance headset can easily be fifty times (17 dB) more sensitive than the instruments usually employed.

THE CIRCUIT



Basically, the “hookup” is a classic two-circuit tuner with variable coupling between the primary (antenna) and secondary (detector) tuned circuits. This is essentially the same architecture used to great effect in the communication receivers of the wireless era. This circuit was almost never used in commercial broadcast crystal sets because of its high parts count resulting in high price.

The primary or antenna circuit consists of inductor L1 and variable capacitor C1. Switch S1 allows the primary circuit to be used either in series or parallel with the antenna and ground connection. The series connection in normally employed, while the parallel arrangement is helpful with shorter antennas. L1 is tapped via switch S2 to provide a range of inductance values.

The secondary or detector circuit comprises inductor L3 and variable capacitor C2. Tapped inductor L2 is in series with the ground returns of both the primary and secondary circuits, and provides a variable mutual inductance which controls the coupling between the two circuits. This feature allows the operator to trade off signal transfer for increased selectivity. The effect is fundamentally the same a achieved with the telescoping coils of the classic “loose coupler”.

The detector is connected to the high-impedance point at the junction of L3 and C2. This applies the maximum available voltage to the detector to help overcome it’s forward junction drop. Although this is the “usual” connection in many sets, it is often counter-productive as the relatively low impedance (10K ohms) of the ubiquitous 2000 ohm headset unduly loads the tuned circuit compromising both signal strength and selectivity. In this set, the detector load is the 100K ohm primary of audio transformer T1. Switch S4 selects either the “external” crystal detector or the “internal” germanium diode.

T1’s low impedance secondary (600 ohms) provides optimal coupling to the extremely sensitive headset included with this radio. Switch S5 may be used to select a medium-high impedance output for use with more conventional headsets.

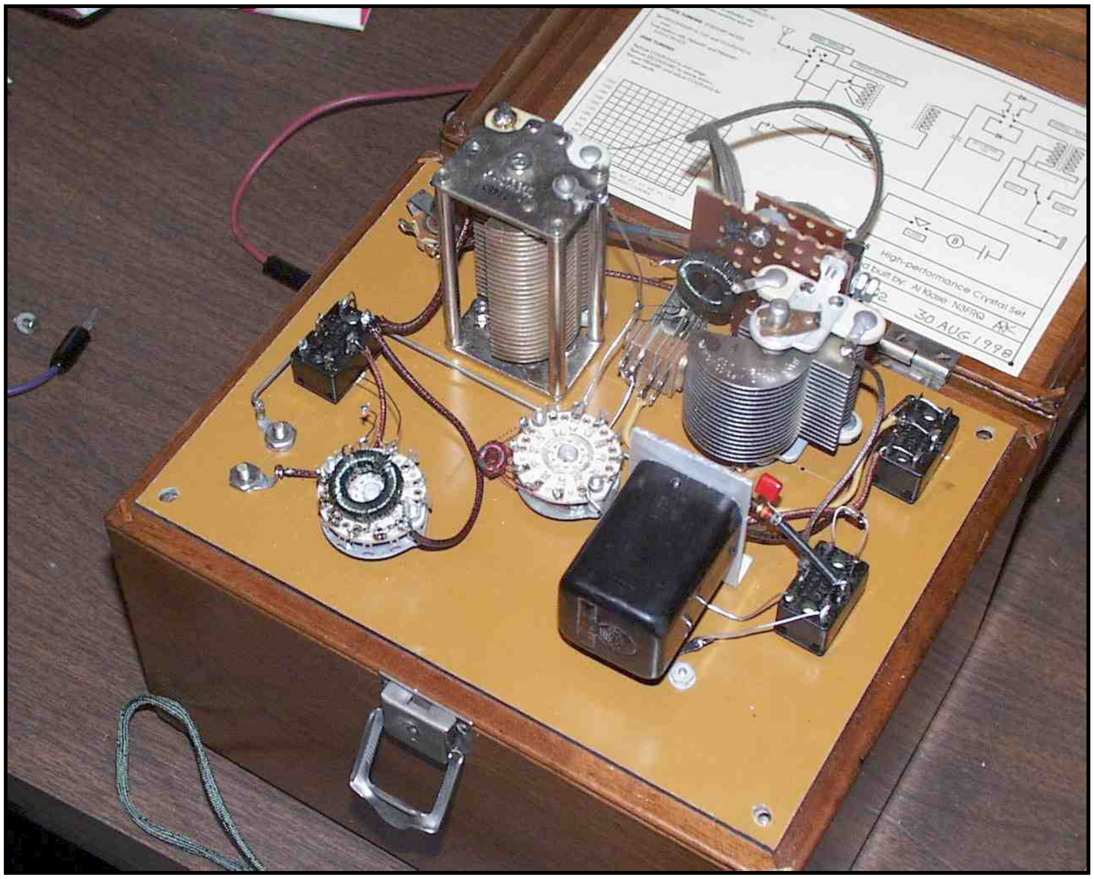
In a double tuned receiver, it can be difficult to find a sensitive spot on the crystal when proper tuning of the primary and secondary has yet to be achieved. The buzzer circuit provides a broadband RF signal to allow adjustment of the detector in the absence of a tuned station.

THE COMPONENTS

A conscious effort was made to use commercial-quality US-made vintage components wherever possible. The wafer switches are ceramic units with silver plated contacts, the variable capacitors are high-end Hammarlunds, the tuning knobs and binding posts are from James Millen, the toggle switches are Cutler-Hammer, the phone jack is from Switchcraft and the audio transformer is a UTC A-12. Even the buzzer is a Western Electric “KS” spec. part. One notable exception is the coils, these are wound on modern ferrite cores to provide optimum performance in a reasonable space.

The headset was assembled from a vintage headband and sound-powered telephone elements from a WWII TS-10 handset. It is as sensitive as any I’ve encountered.

CONSTRUCTION



The radio is assembled in an walnut box with a leather carrying handle that once housed a Leeds and Northrup Wheatstone bridge. The bulk of the components are mounted to the Bakelite front panel. Construction technique is best described as 1950’s “model shop”, and is much nicer than an average homebrew set or engineering-lab prototype.

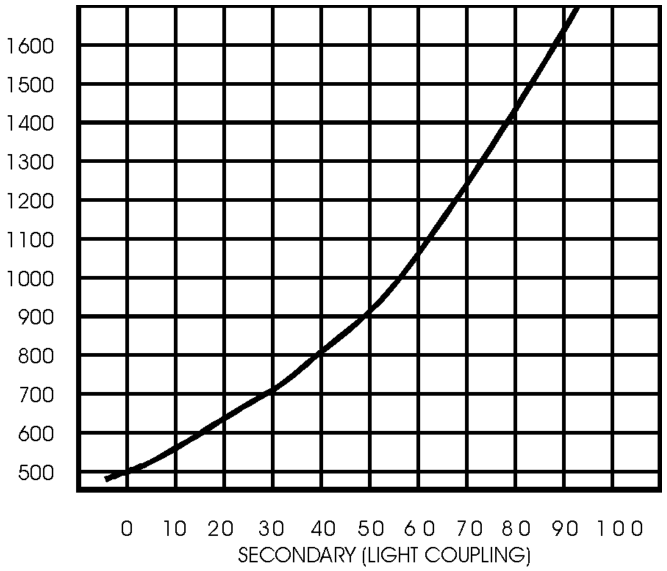
OPERATION

Connect antenna, ground and headset. Select SERIES for long antennas PARALLEL for short.
If the EXTERNAL detector is selected, activate the BUZZER while manipulating the catswisker to locate a sensitive spot on the crystal.

To easily locate strong signals, set the SECONDARY capacitor to 100 and COUPLING to maximum (fully clockwise). Tune the set with the PRIMARY capacitor and PRIMARY INDUCTANCE. With this setup, the inductance L3 acts as an untuned secondary to L1. This was known as the “standby” mode in the classic marine wireless receivers.

To take full advantage of the available sensitivity and selectivity, reduce the COUPLING control to midrange and reduce the SECONDARY capacitor to retune the station. Then, adjust the PRIMARY and COUPLING controls for best results. Tuning a receiver of this sort across the band is definitely a two-hand affair. It’s sometimes helpful to rock one knob back and forth while slowly tuning the other.

The tuning of the secondary circuit is fairly repeatable if the coupling is kept light. The tuning chart inside the lid can be used to set the secondary to a desired frequency. It’s calibration is based on position 2 (from the left) of the coupling switch.



COIL DETAILS

The coils are wound on ferrite toroid cores from Amidon associates. L1 is 75 turns of #26 enameled wire on an FT-82-61 core tapped every 15 turns. Inductance is approximately 400 uH maximum. L2 is 25 turns of #30 on an FT-37-61 core tapped at 3, 10, 15, and 20 turns. Inductance is approximately 35 uH maximum. L3 is 68 turns of #26 on an FT-82-61 core. Inductance is approximately 290 uH.

Crystal Radios & Tube Radios

Crystal Radio Trouble Shooting Page

Here are a few tips to check on. These are common mistakes or problems.

We'll start with the most common problems and work down.

Antenna-

1) Is it long enough? It should be at least 50 feet or so. If it's only 40 feet, don't worry try it anyway. It will probably be OK.

2) Is it high enough? Should be up as high as you can get, but be safe. Don't get near electrical lines etc. Min. would be 8 or 10 feet and still work. I've even seen them thrown out the window and just hanging there and work. It will depend on how close and strong your radio stations are .

3) Make sure your antenna is not "grounded out". That is, no part of the antenna (bare wire) is touching anything like a fence or tree. This will "ground out" the antenna.

Ground-

The other part of the antenna system is the ground. This can be a water pipe or a rod pounded in the ground. If you use a water pipe, make sure your water pipes are not PVC which is a plastic. If you pound a rod in the ground, it will need to be at least 4 or 5 feet deep. Another ground is the screw in the middle of a plug in the wall outlet, but the outlet must be a grounded type to work.

Insulation-

1) Did you strip the insulation off the ends of the wires before connecting them?

2) Did you remove the insulation off the wires at the "Taps". The Taps are where the alligator clip connect on to
the coil?

I know this sounds too simple to be true, but some of us out there know nothing about electrical properties so…….we will check.

Connections-

1) Are all your connections sound? Metal to metal!!!

2) Are they correct? Check them 3 or 4 times at least. This is the most common error and sometimes the hardest to find!

Coil Windings-

1) Did you wind the right amount of winding on the coil?

2) Are they fairly tight to one another. You can't "scatter wind" the coils. One wind neatly along the side of the
next.

Now for the real problems. The rest of the components. That would be the 1) earphone, 2) the diode, 3) and the resistor.

The "Earphone"-

Here the most common mistake is to take an earphone from Radio Shack or a set of headphones or "ear buds" from a regular radio and try to use them. Without getting into a big technical explanation, you can't use them. It must be a "crystal" earphone. Some times called a "ceramic" earphone. They are much more sensitive than stereo earphones or ear buds. You can test your earphones buy removing them from the radio and putting the earphone in your ear. Next take the two wire ends of the cable coming out of the earphone and tap them together a few times. You should hear a "clicking" sound. This is how sensitive they are. DO NOT USE A BATTERY TO TEST THEM. This will mess them up. I have seen lots of earphones brand new that did not work.

Resistor-

The most common mistake here is that you used too small of a resistor here. In other words the values of the ristor is less than 47,000 ohms (47k). The resistor bands should be yellow, purple, orange with a gold or silver band last. Using a resistor of lesser value will "short out" the radio and it will not function. You can also leave out the resistor and it will work, just not as good.

Diode- (most look like they are made from glass, with one black band)

This is almost impossible for a beginner to check without a meter of some kind. If you have a meter that reads "continuity", then put the diode on it and it should read in one direction, but if the diode is turned around it will not read. If you don't have a meter all you can do is try and replace it.

Second most common mistake with the diode is… It has to be a germanium diode to work. A silicon diode used in power configurations will not work (well, not very well).

This radio has been made by hundreds of people and it has worked. Sometimes after a mistake is found, but it will work.

I hate to say this, but maybe you don't have a radio station close buy. If you are in the middle of farm country and no station are near you (more than 100 miles) you might not be able to pick up any thing with this set. 99.999% of the time this is not the case.

If you are still having problems, email me. Maybe I have a part or so that you can have and try……or ask questions at "Tap N Tap" at http://www.midnightscience.com/rapntap/

They have a beginner's forum that is great!!

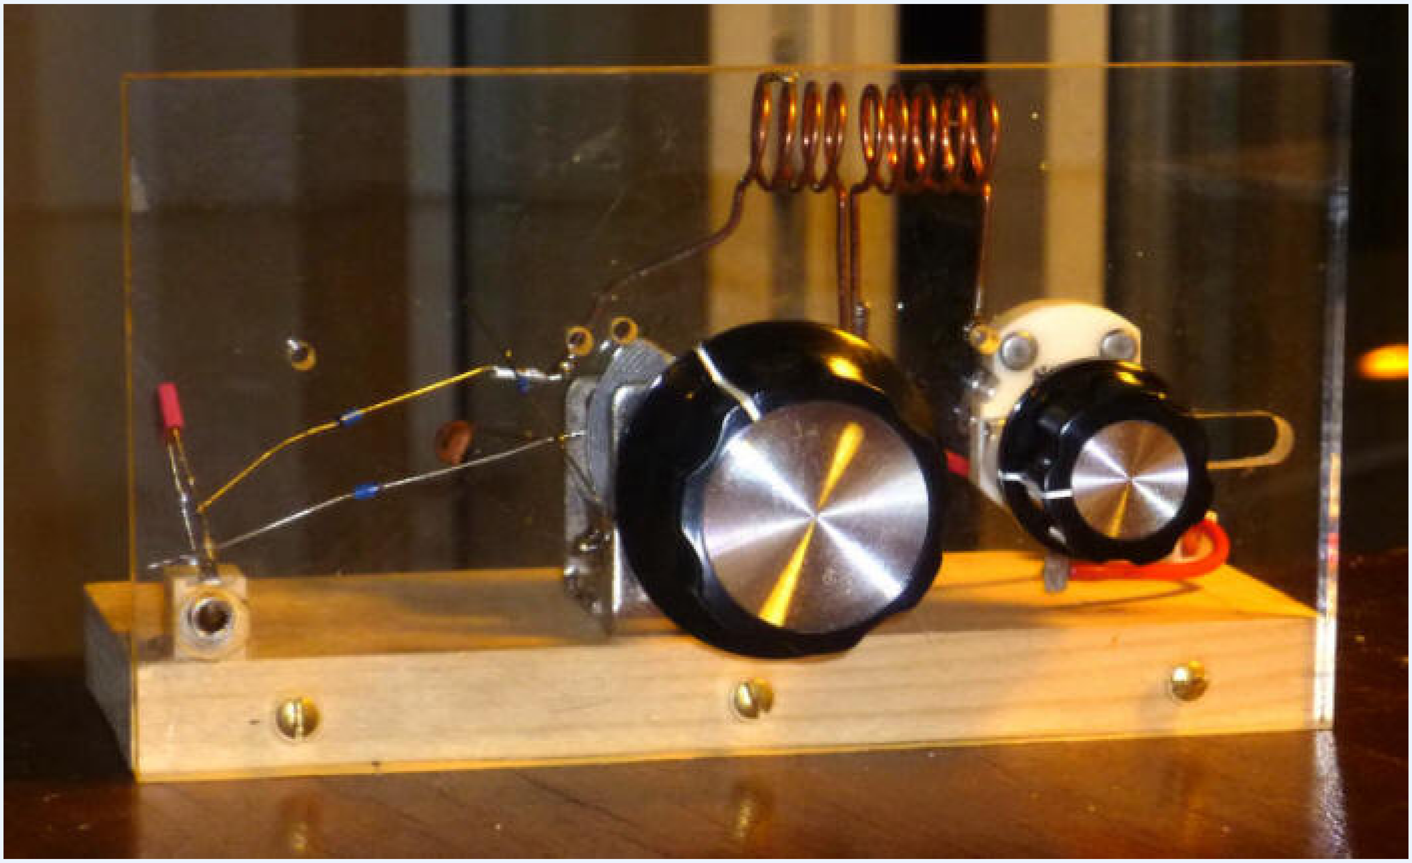
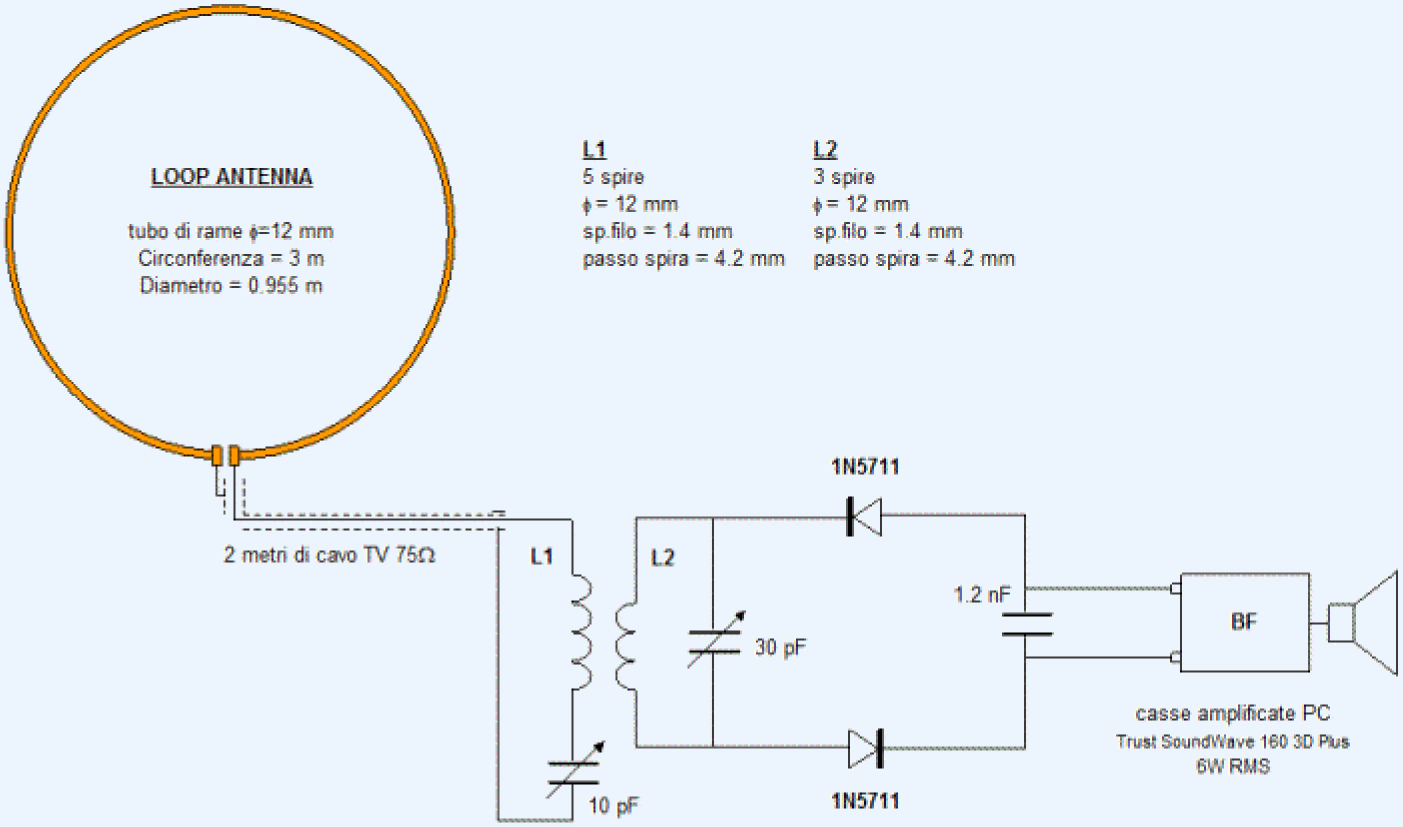
Readers' Projects - Sophie's radios

Crystal receiver for FM

A project by **Giacomo Cavuoti**



Following Leonardo's invitation I made this simple crystal receiver for FM (click on the diagram below to see it enlarged).



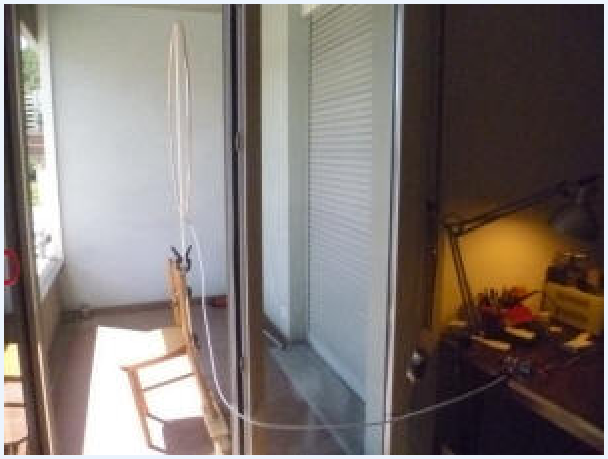
LOOP ANTENNA
tubo di rame ϕ=12 mm
Circonferenza = 3 m
Diametro = 0.955 m
L1
5 spire
ϕ = 12 mm
sp.filo = 1.4 mm
passo spira = 4.2 mm
L2
3 spire
ϕ = 12 mm
sp.filo = 1.4 mm
passo spira = 4.2 mm
1N5711
2 metri di cavo TV 75Ω
L1
L2
1.2 nF
BF
30 pF
casse amplificate PC
Trust SoundWave 160 3D Plus
6W RMS
10 pF
1N5711

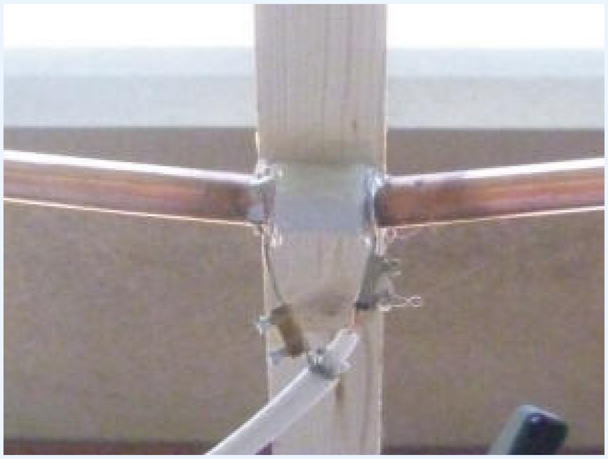
The receiver is "powered" by a full wave loop antenna consisting of a single circular coil made of 3 meters of copper pipe for hydraulic systems (measured inductance of about 3 uH). The support is a simple 2-meter long fir-wood strip, 3 cm wide and 1 cm thick, to which the copper rim has been fixed with insulating tape. Another solution to realize the loop antenna in a simple and instantaneous way is to use an aluminum strip 2 mm thick and 2 cm wide. The detectors are two *Schottky* diodes type 1N5711, particularly suitable for VHF thanks to the low capacity (about 2pF). They are currently in production and therefore easy to find. The receiver was tested in a "stiff" situation with the antenna exposed in a recessed balcony (3 x 1.6 meters) on the fourth floor of a 6-storey reinforced concrete building surrounded by other buildings constructed of reinforced concrete walls. As you can see and hear from the two videos I uploaded on Youtube:

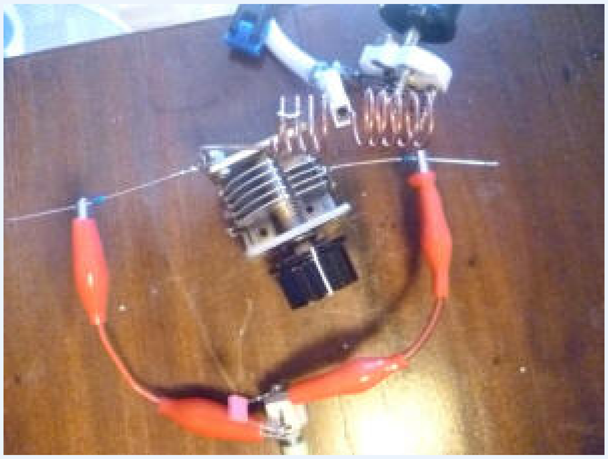
http://www.youtube.com/watch?v=YNiuRoIp36E

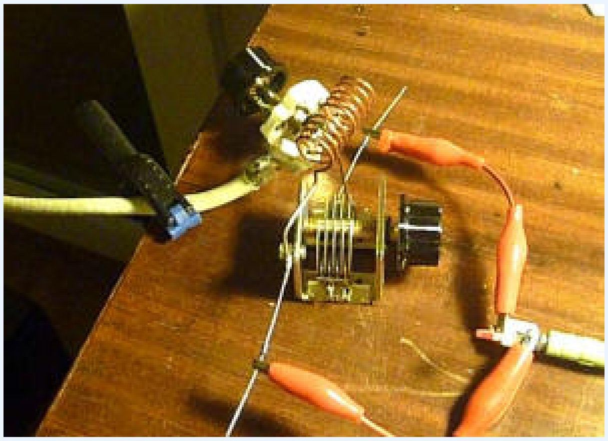
http://www.youtube.com/watch?v=SJwx8_3mCfI

the reception is good as well as the selectivity, thanks to the appropriate coupling, but very easy to find, between the antenna coil L1 and that of L2 tuning. The audio amplification has been entrusted to two small speakers amplified by PC. The following photos show the first working prototype mounted "in the air" (click on the images to see them better). The photo below the title instead shows an aesthetically more accurate realization.









For any clarification, do not hesitate to contact me. Giacomo Cavuoti

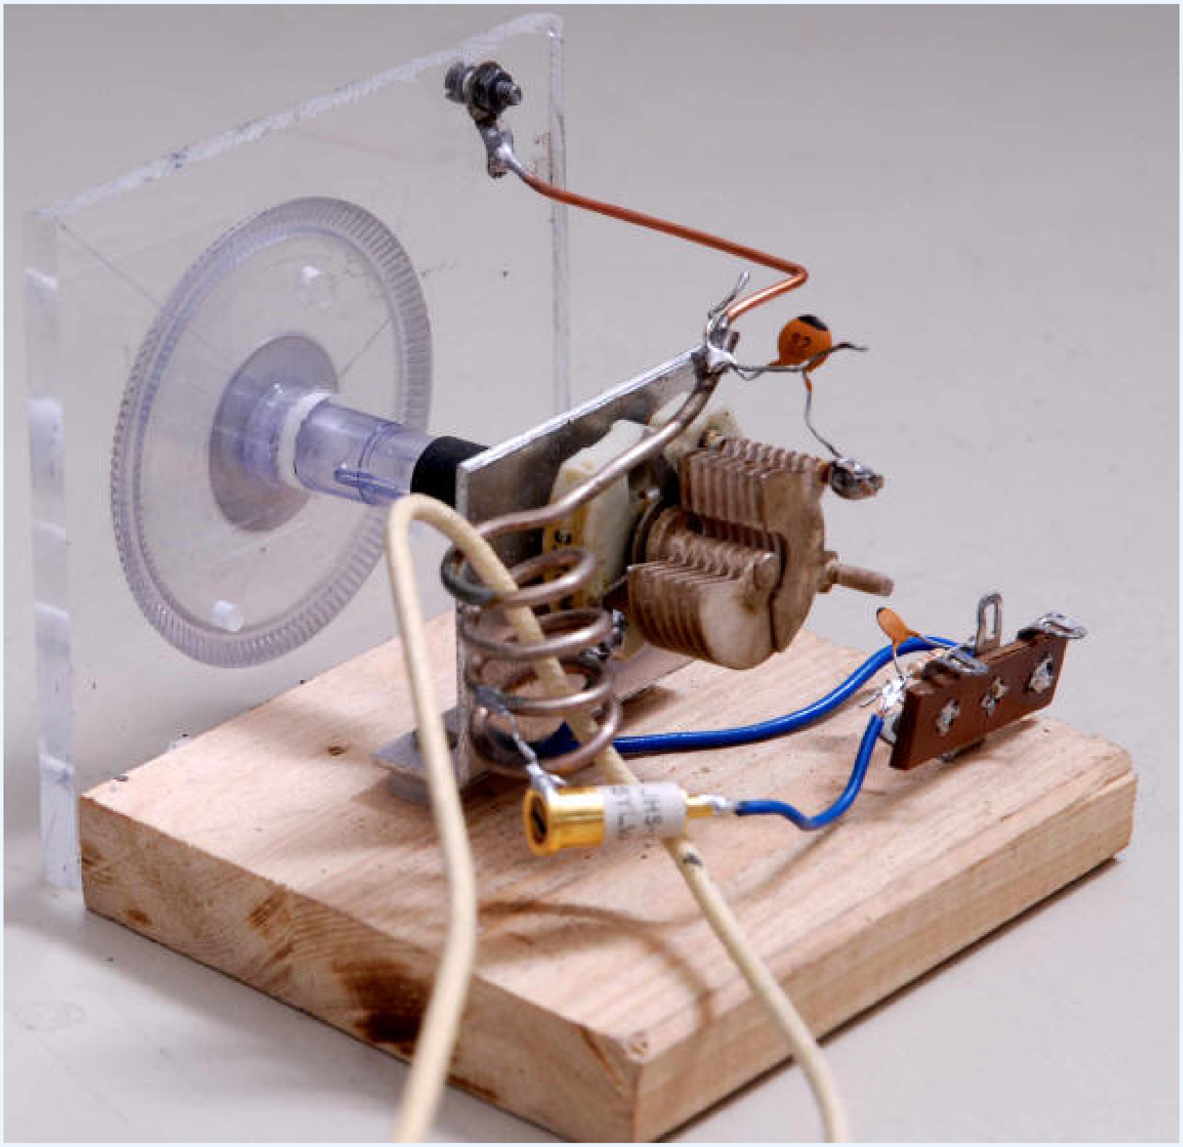
Simple crystal receiver for FM

Carlo Bramanti



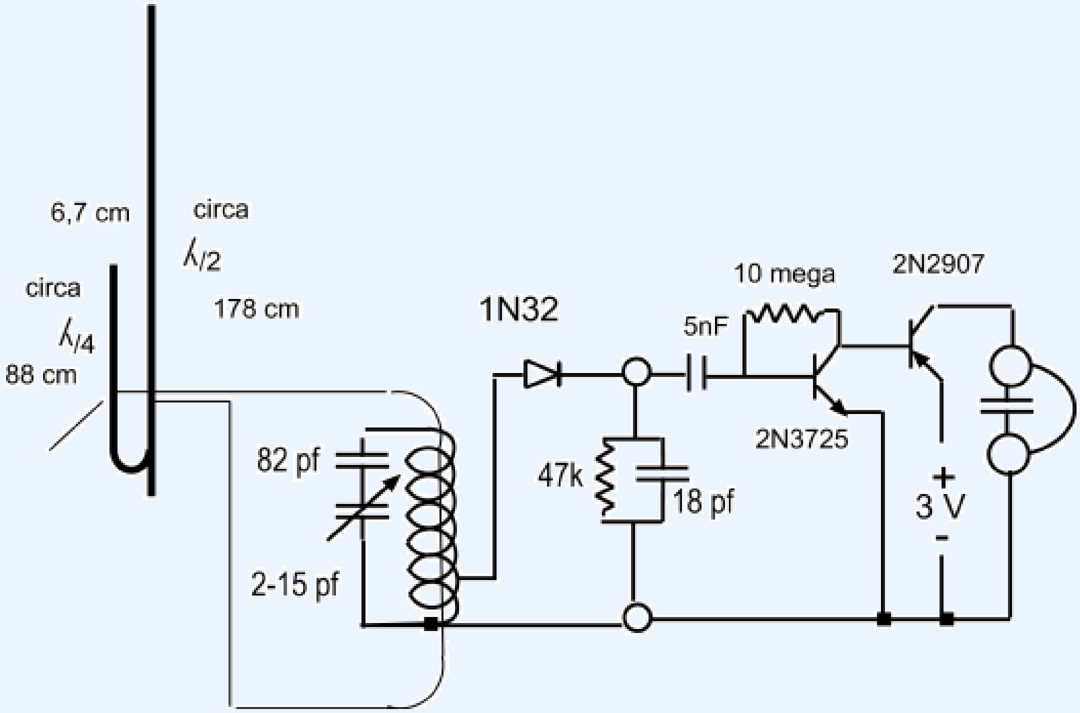
After the success obtained in the realization of the "galena" FM with the resonant cavity, I had promised myself to try also with a simple LC resonant circuit. One of my galena mates favored what he had built without success and I set about making it work.

Operation

With the experience that the audio signal resulting from this detection is very low, I immediately applied the two-transistor amplifier I have already described on these pages. With the fully extended stylus it did not actually work, but by lowering it, you already felt something.

The link

When I connected it to the J antenna it worked fine. The connection that gave me the best results was a simple conductor loop over eighty cm (about ¼ wave), passed through the resonant coil. If we use a cable to move the antenna away, the loop connects directly to the cable. I have no particular experience on these frequencies and I think that those who have more can still improve performance. In any case they are already adequate, even if slightly inferior to that of the cavity, with the advantage that everything is much more comfortable and pleasant.



The theory

Normal AM revelation can not reveal weak signals with the consequence that it is useless to amplify after the revelation, since it increases only the volume and not the sensitivity. Instead the detection of the FM also handles very weak signals: therefore, amplifying after the detection, all the weakest stations appear. The amp that I made amplifies a lot (in AM it also acts as a detector, but in FM it must be preceded by a diode); it can be powered by a 3 V lithium drain and it consumes very little: it is even sufficient to disconnect the earphone for almost zero consumption. This makes the use of a switch superfluous.

J antenna

It is an antenna that is easy to realize by bending a copper pipe by fontaniers, with a diameter of 6 o 8 mm. Fixing to a pole or base does not require isolation.

The diode 1N32

I obtained an additional advantage by replacing the germanium diode OA85 with the one with contact tip silicon 1N32, a little old but available and used as a mixer for the K band.

NOTE

In the aforesaid realization the frequencies from 88 to 104 Mc are listened with a rotation of the variable of only 45 degrees, or half of the excursion. Above I hear nothing.

The excursion with trimmers and padders should therefore be extended, while maintaining the optimal L / C ratio.

Realization:

Coil in silver wire from 2 mm.

Average diameter 14 mm

Length 19.5 mm

Number of turns 4

1 ½ coils outlet from the municipality

Ground connection not necessary

Proposal

I would have made the coil with three turns of three millimeters, diameter three cm, length three cm. The Q would be one and a half times higher, which on balance, would improve performance slightly; except try, in this discipline you never know!

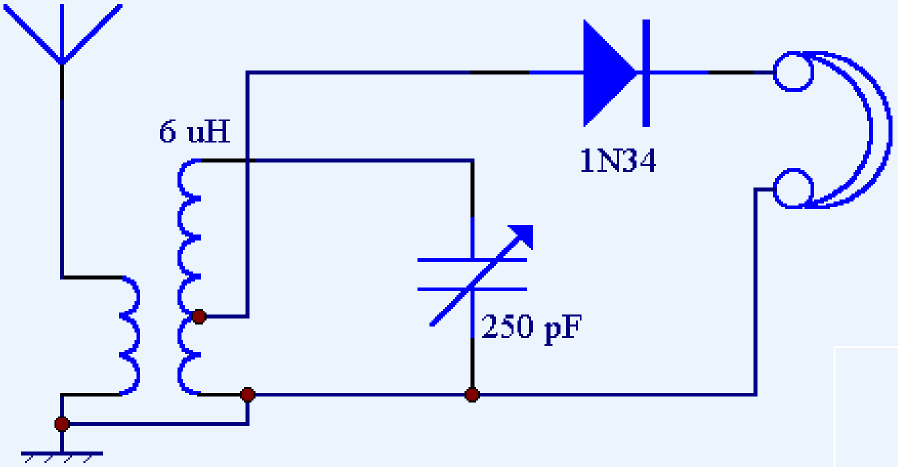
Crystal Radio for Short Waves

A project by Leonardo Mureddu

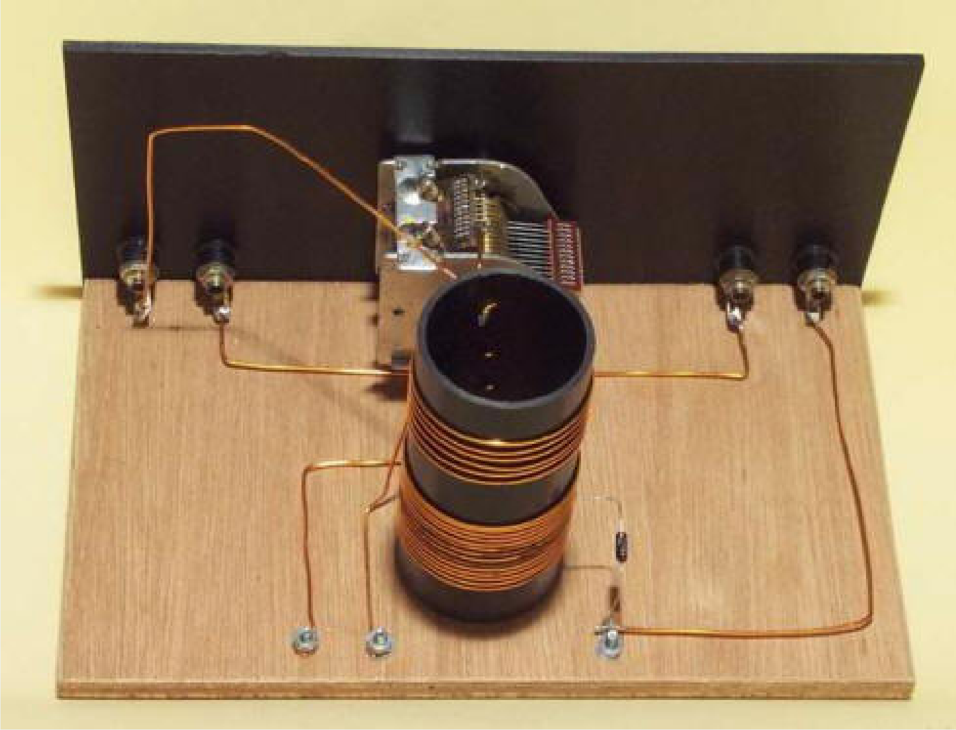
For those who enjoy listening to distant and mysterious stations, the bands of the Court Waves undoubtedly offer an endless series of emotions. In fact, the propagation phenomena favor precisely these frequency bands, between 5 and 20MHz (with a wavelength of between 20 and 60 meters), transporting them at intercontinental distances thanks to a series of reflections that occur between the ground and the upper part of the atmosphere (ionosphere). It may therefore happen to receive distinctly in Italy, perhaps only for a few minutes, transmissions from Australia, China or America. Short wave broadcasts were not immediately introduced in the history of radio, indeed for all the '20s the big companies continued to bet on long waves for intercontinental transmissions, and on medium waves for local broadcast broadcasts. It was only in the 1930s, with the development of large planetary-scale communication networks that short waves were chosen as privileged vehicle for transmissions between the motherland and the colonies or the army at war, and for communications between allied nations. The best radio receivers were therefore equipped with numerous wave ranges capable of tuning and receiving broadcasts from all over the world. Nowadays the frequencies of the short waves, although now almost completely forgotten and often absent in the domestic tuners, are still very popular and full of programs in all languages.



The construction of a crystal receiver for shortwaves is a fairly easy undertaking and can give great satisfaction, especially to those who delight in the so-called "DX", ie listening to broadcasts from great distances.

Scheme of principle

The project I present here is very simple and has no great pretensions, but it can serve as a starting point for experimenting with more complicated and efficient devices. The technique used is somewhat different from that used for medium waves, because higher frequencies require some constructive measures to minimize losses. The scheme is very similar to that of any medium wave receiver. What changes is the inductance of the coil and the construction technique. The receiver consists of an input transformer with a tuned secondary and an intermediate socket for the detector.



Constructive notes

To obtain satisfactory results, a few rules must be followed, among which the most important is to make a compact assembly using coarse rigid wire for the connections between the various components. In the prototype shown above, 1mm diameter enamelled copper wire was used to make both the coils and the connections. Enamelled copper is preferable to bare or tinned copper, *due to the skin effect*. In fact, the enamel preserves from the oxide the surface of the wire on which the conduction takes place. For the same reason, the use of PVC insulated hard wire is not recommended. It is advisable to mount it on an insulating base, in order to reduce losses due to the proximity effect. The use of a variable air-cooled condenser is strongly recommended, but acceptable results can also be obtained with a miniature capacitor with a polyester dielectric (for transistor radios). The old capacitors with solid dielectric (bakelite or other) must be avoided, as they have too many losses at high frequencies. The tuning coil is made of 14 turns of 1mm wire on a good 4cm diameter support; the turns are spaced so as to have a total length of about 3cm. The detector plug is made at the fifth turn. The antenna coil, wound on the same support, is made up of 6 turns of the same wire, even these slightly spaced. It will be good to equip the variable capacitor with a rather large knob, since in short waves the tuning is always quite critical. The detector plug is made at the fifth turn. The antenna coil, wound on the same support, is made up of 6 turns of the same wire, even these slightly spaced. It will be good to equip the variable capacitor with a rather large knob, since in short waves the tuning is always quite critical. The detector plug is made at the fifth turn. The antenna coil, wound on the same support, is made up of 6 turns of the same wire, even these slightly spaced. It will be good to equip the variable capacitor with a rather large knob, since in short waves the tuning is always quite critical.

Testing

After connecting the antenna (the same used for the medium waves) and the ground, slowly rotate the tuning knob: it should be possible to clearly capture some stations in various languages. Selectivity should be sufficient to separate near-frequency transmissions. You will notice that any received station is subject to a progressive fading, until it disappears altogether and then reappears or replaced by another station. This phenomenon is called "evanescence" (in English "fading"), is typical of short waves and is due to the propagation of ionospheric waves, which are subject to interference phenomena.

I invite the fans to propose changes and improvements, which I will gladly welcome in these pages.

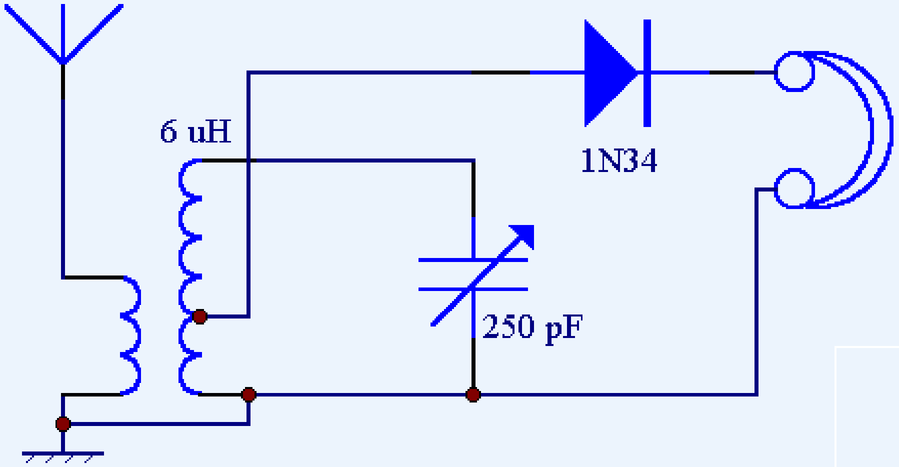
Radio a Cristallo per Onde Corte

Un progetto di Leonardo Mureddu

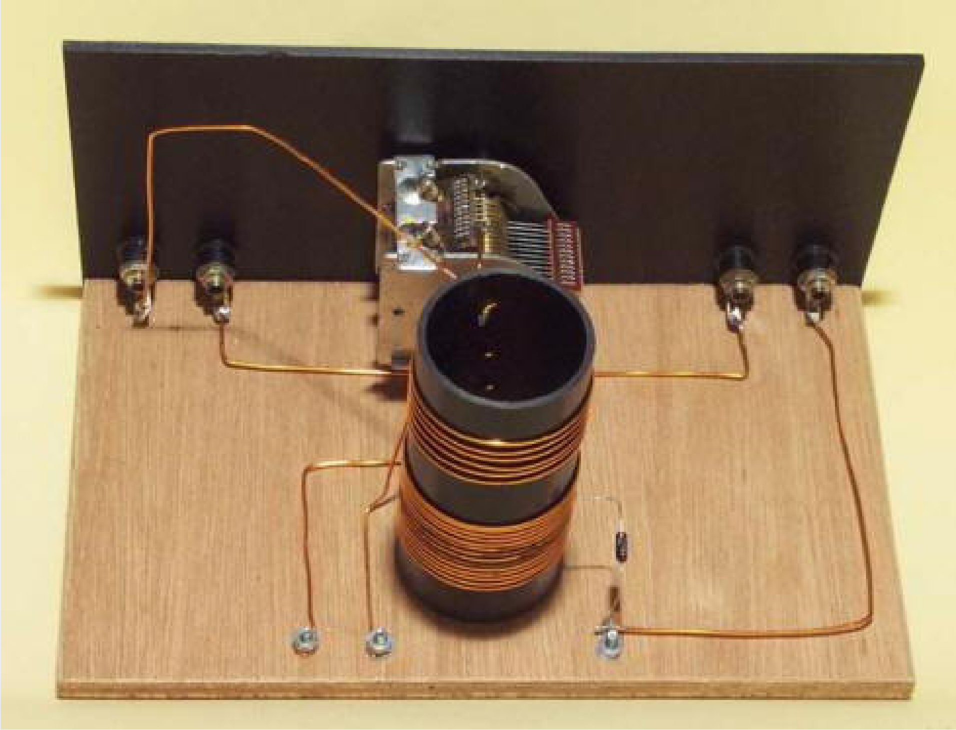
Per coloro che amano l'ascolto di stazioni lontane e misteriose, le bande delle Onde Corte offrono senza dubbio una serie infinita di emozioni. Infatti i fenomeni della propagazione privilegiano proprio queste bande di frequenza, comprese tra i 5 e i 20MHz (con lunghezza d'onda compresa tra i 20 e i 60 metri), trasportandole a distanze intercontinentali grazie ad una serie di riflessioni che avvengono tra il suolo e la parte alta dell'atmosfera (ionosfera). Può quindi capitare di ricevere distintamente in Italia, magari solo per pochi minuti, trasmissioni provenienti dall'Australia, dalla Cina o dall'America. Le trasmissioni ad onde corte non vennero introdotte subito nella storia della radio, anzi per tutti gli anni '20 le grandi compagnie continuarono a scommettere sulle onde lunghe per le trasmissioni intercontinentali, e sulle onde medie per le trasmissioni a diffusione locale. Fu solo negli anni '30, con lo sviluppo delle grandi reti di comunicazione a scala planetaria che le onde corte furono scelte come veicolo privilegiato per le trasmissioni tra la madrepatria e le colonie o l'esercito in guerra, e per le comunicazioni tra nazioni alleate. I migliori ricevitori radio erano quindi dotati di numerose gamme d'onda in grado di sintonizzare e ricevere trasmissioni da tutto il mondo. Al giorno d'oggi le frequenze delle onde corte, sebbene ormai quasi del tutto dimenticate e spesso assenti nei sintonizzatori domestici, sono ancora molto frequentate e ricche di programmi in tutte le lingue.



La costruzione di un ricevitore a cristallo per le onde corte è un'impresa tutto sommato abbastanza facile e può dare grandi soddisfazioni, specie a chi si diletta nei cosiddetti "DX", ossia l'ascolto di trasmissioni provenienti da grandi distanze.

Schema di principio

Il progetto che presento qui è molto semplice e non ha grandi pretese, ma può servire come base di partenza per la sperimentazione di apparecchi più complicati ed efficienti. La tecnica usata è un po' diversa da quella usata per le onde medie, perché le frequenze più elevate richiedono alcuni accorgimenti costruttivi per minimizzare le perdite. Lo schema è molto simile a quello di qualunque ricevitore per onde medie. Ciò che cambia è l'induttanza della bobina e la tecnica costruttiva. Il ricevitore è costituito da un trasformatore d'ingresso con secondario accordato e presa intermedia per il rivelatore. Con i valori indicati (6 microhenry per l'induttanza e 250 pF per il condensatore variabile) si copre quasi tutta la gamma delle onde corte, da 5 a 15 MHz.



Note costruttive

Per ottenere risultati soddisfacenti occorre attenersi a poche regole, tra cui la più importante è quella di realizzare un montaggio compatto utilizzando filo rigido grosso per i collegamenti tra i vari componenti. Nel prototipo mostrato qua sopra è stato usato del filo di rame smaltato da 1mm di diametro per realizzare sia le bobine che i collegamenti. Il rame smaltato è da preferire al rame nudo o a quello stagnato, per via dell'*effetto pelle*. Infatti lo smalto preserva dall'ossido la superficie del filo su cui avviene la conduzione. Per lo stesso motivo non è consigliabile l'uso di filo rigido isolato in PVC. E' bene realizzare il montaggio su una basetta isolante, in modo da ridurre le perdite per effetto di prossimità. L'uso di un condensatore variabile ad aria è fortemente consigliabile, ma si possono ottenere risultati accettabili anche con un condensatore miniatura con dielettrico in poliestere (per radio a transistor). Sono da evitare assolutamente i vecchi condensatori con dielettrico solido (bakelite o altro), perché presentano troppe perdite alle alte frequenze. La bobina di sintonia è realizzata con 14 spire di filo da 1mm su un buon supporto da 4cm di diametro; le spire sono distanziate in modo da avere una lunghezza totale di circa 3cm. La presa per il rivelatore è realizzata alla quinta spira. La bobina d'antenna, avvolta sullo stesso supporto, è costituita da 6 spire dello stesso filo, anche queste leggermente distanziate. Sarà bene dotare il condensatore variabile di una manopola piuttosto grossa, dal momento che in onde corte la sintonia è sempre alquanto critica.

Collaudo

Collegata l'antenna (la stessa usata per le onde medie) e la terra, ruotate lentamente la manopola di sintonia: dovrebbe essere possibile captare con chiarezza alcune stazioni in varie lingue. La selettività dovrebbe essere sufficiente a separare trasmissioni vicine in frequenza. Noterete che qualunque stazione ricevuta è soggetta ad un affievolimento progressivo, fino a scomparire del tutto per poi riapparire o venire sostituita da un'altra stazione. Questo fenomeno si chiama "evanescenza" (in inglese "fading"), è tipico delle onde corte ed è dovuto alla propagazione delle onde ionosferiche, che sono soggette a fenomeni di interferenza.

Invito gli appassionati a proporre modifiche e miglioramenti, che accoglierò molto volentieri in queste pagine.

L.M.

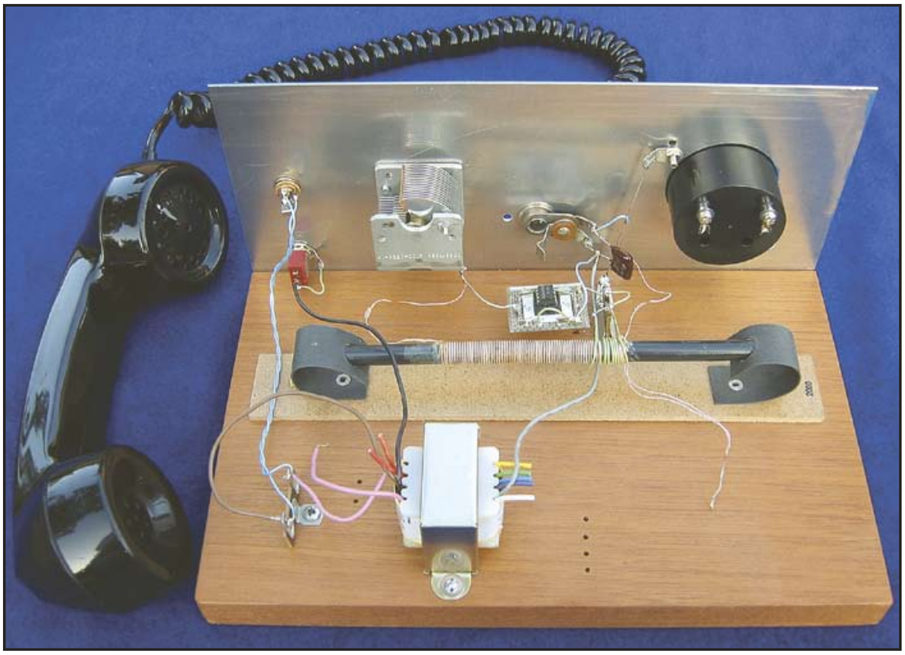
High Sensitivity Crystal Set

Build a "crystal radio" that does not require an outside antenna or ground by using a new zero-voltage-threshold MOSFET.

Bob Culter, N7FKI

If you are like me, you may have been bitten by the "radio bug" while building an AM broadcast band crystal set. In my case, I was using a galena "cat's whisker" detector.[1] Such a radio typically required a long outside antenna and ground rod or water pipe ground connection to function, even with the use of a low-threshold (0.3 V) germanium detector diode such as the well-known 1N34A.

To rekindle the spark of your youth or to interest young people in radio, consider building a radio that doesn't need an outside antenna or ground that might be hard to come by with modern high-density housing, antenna restrictions, and the danger of power line proximity or lightning. Fortunately, a new detector has been developed that does just that.



Rear view of the AM band high sensitivity crystal set showing a GTE telephone handset as the headphone. The panel meter is not used for this project.

Anyone who has experimented with simple crystal sets knows that there is a trade-off between sensitivity and selectivity, or the ability to separate stations that are close in frequency. To understand that, refer to Figure 1, the schematic diagram of a typical crystal set. For highest sensitivity, it is desirable to place the detector diode at the top of the LC resonator (which provides the means for selectivity) where the maximum RF voltage appears with the hope of exceeding the 0.3 V threshold of the detector diode. Placing the detector and headphone load at the top of the resonator at point A results in "de-Q-ing" the resonator, largely destroying selectivity.[2] Placing the detector at a tap point on the inductor, typically 10% of the way up from the ground end at point B, results in much less loading of the resonator and preserves selectivity. Unfortunately, the top of the resonator must now see 3 V peak in order for point B to provide 0.3 V to the detector, so sensitivity is severely affected.

Referring to Figure 2, it is possible to have your cake and eat it, too, with a circuit using the newly introduced ALD110900A zero-threshold-voltage MOSFET IC made by Advanced Linear Devices.[3] Figure 2 shows the circuit topology, which was motivated by a similar circuit using a JFET and battery gate bias configuration developed by David W. Cripe, NE4AM (formerly KC3ZQ).[4] The circuit is essentially a synchronous rectifier. It uses the high voltage end of the resonator formed by a ferrite antenna rod, L1, and tuning capacitor, C1, to drive the gate of the MOSFET, resulting in rectifier action from the channel. The MOSFET source and drain replace the anode and cathode of the usual 1N34A diode connected to a separate 8-turn winding on L1, which is equivalent to the 11% tap point on L1.

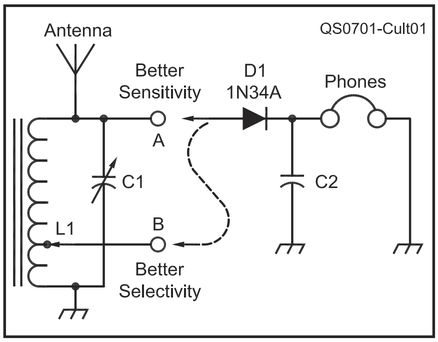


Figure 1 — Schematic diagram of a typical crystal set with diode connected to A for sensitivity and B for selectivity.

In a synchronous rectifier, the MOSFET acts like a switch, turning on during the positive half cycles of the applied RF voltage and off during the negative half cycles. The 2000 pF capacitor, C2, integrates the pulsating dc to create the audio modulation in the headphones. In this circuit, the gate voltages are not high enough to create a perfect switch, and so the MOSFET modulates the resistance of the source-drain channel over some impedance range whose average approximates the impedance of the headphone load for maximum energy transfer.

In the radio shown in Figure 2, both FETs of the dual-FET ALD110900A, U1, have a common-source connection and are connected in parallel to better match the headphone impedance. The resulting detec-

---

[1] Notes appear on page 33.

From January 2007 QST © ARRL

tor has an off resistance (0 V on the gate) of 52 kΩ and an on resistance of 250 Ω with a peak voltage of +5 V on the gate. In this radio, the maximum measured gate voltage is only 0.25 V peak, so the channel modulation creates an average source impedance to the headphones of approximately 25 kΩ. An antique pair of 25 kΩ headphones can be used directly if you have them, but most headphones will require an impedance transformer, in this case the multi-tapped Bogen T-725 public address matching transformer.

Most of the other parts are scarce or no longer in production. You may have to wind your own ferrite rod to emulate the J. W. Miller 2000 antenna rod or adapt the rod from an old AM transistor radio. To wind your own, obtain an Amidon Associates ferrite rod, part number R61-050-750, which is 7.5 inches long and 0.5 inch diameter.[5] Using 15/44 or 15/46 Litz wire, wind 70 turns in the center of the rod spaced to fill 3 inches.[6] The 8-turn secondary can be ordinary magnet wire wound over primary, on the lower end of the main coil. A high-quality 365 pF air variable tuning capacitor can be purchased or obtained from an old radio. A good junk box and resourcefulness are in order.

There is No Magic

Even though the zero threshold of the MOSFET detector greatly improves performance, the available power is low and the acoustic power from the headphones depends on extracting the greatest efficient from every component in the radio.

The use of high-sensitivity earphones is critical to the success of your radio. The best inexpensive stereo earphones have a sensitivity of 108 dB sound pressure level per milliwatt (SPL/mW), where 0 dB SPL is 20 microPascals SPL or the 0.0001 pW/cm^2 threshold of human hearing, and an impedance of 8 to 64 Ω. Although these can be matched to the radio with the Bogen T-725 transformer (which has a separate 8 Ω winding) and offer superior bass response, this is a very low sensitivity compared to what is desired. The receiver of an old dial type or early model tone access pad telephone may be a better choice. I have used an audio signal generator and RadioShack sound level meter to measure the sensitivity of telephone receiver elements such as the GTE D-51030A or Western Electric U-1 or LB-1, which can be obtained from old telephones in thrift shops for several dollars. The sensitivity is about 122 dB SPL/mW or 14 dB better than stereo headphones, although the response is limited to about 3 kHz. If we assume an earphone aperture of 1 cm^2, this is an efficiency of 16% in converting electrical power to sound power. The Knowles Acoustics CM-3152 balanced-armature element

C2 — 0.005 µF ceramic capacitor (or two 0.0022 µF capacitors in parallel).
D1 — 1N4152 silicon diode (see text).
J1 — Mono headphone jack.
L1 — AirDux coil, 19.5 turns, 2 inch diameter, 10 turns/inch, tapped at 5 and 8 turns.
L2 — 9 turns FT 50-43 toroid (see text).
T1 — Bogen T-725 public address matching transformer. (Note: BLU tap, 5 kΩ, is different from AM version.)
U1 — ALD110800APCL Quad MOSFET (Mouser 585-ALD110800APCL).

Making it Even Better

An additional improvement in received volume can be obtained by coupling a high-Q tunable loop antenna to the ferrite rod antenna in the manner of a "loose coupler." I have used an 11-inch diameter Select-A-Tenna loop to obtain 65 dB SPL A-weighted volume (about normal conversational volume with 3.3 µW electrical input) from a 5 kW station 3 miles away.[8] Replacing the MOSFET with a 1N270 germanium diode resulted in no discernable output. It has been possible to hear seven local stations in a 25 mile radius with no difficulty. You can search for your station locations on the FCC Web site.[9] Signals with 30 dB SPL (whisper level) volume are quite listenable with only 0.1 µW electrical input to the earphone. It only takes 5 to 10 mV peak-to-peak on the source of the MOSFET to provide an adequate volume level.

You can make your own "amplifying" tunable loop antenna with a 23 inch diameter wooden quilting hoop. This will come apart as an inner hoop and a split outer hoop with wooden ends and a tightening screw. Close-wind 12 turns of AWG no. 24 magnet wire in the middle of the outside surface of the inner hoop and tape the ends in place. Next, at about 2 to 3 inch intervals, carefully separate the turns to spread them evenly across the ¾ inch width of the inner hoop and tape in place as you proceed. Mount the outer hoop over the inner hoop and tighten in place using the long metal screw. Mount a 365 pF air variable tuning capacitor on the large wooden blocks as shown in Figure 3. It will be necessary to drill an additional hole in the mounting blocks to pass the shaft of the capacitor. Use a shaft extension with a knob to provide tuning ability. Solder the two ends of the coil to the stator and rotor of the capacitor.

The auxiliary loop that you have created has an inductance of about 240 µH and will tune the entire AM broadcast band with a 365 pF capacitor. Place the loop off the end of the crystal set's ferrite loop. A line across the diameter of the loop should point to the desired station. Tune in a station on the crystal set and peak the volume by tuning the large loop. The received signal strength will be dramatically increased. With this larger loop, the station previously mentioned increased in volume to 72 dB SPL using a GTE telephone receiver.

Shortwave Version

I have constructed a version of this receiver to cover the 90 to 40 meter shortwave spectrum. Figure 4 is a picture of this receiver and Figure 5 shows the schematic diagram and parts list. Shortwave performance is difficult, especially at my US West Coast location where few powerful shortwave stations can be heard and severe fading is evident. With this receiver I was able to reliably receive HSK9, Radio Thailand, broadcasting from the 250 kW International Broadcasting Bureau (IBB) transmitter in Delano, California on 5890 kHz. I was using an external 40 foot wire antenna.

The detector consists of four MOSFETs in parallel using the quad version of the detector IC in order to better match the lower resonator impedance. The source tap point was also changed to the 25% point on the inductor. The resulting loaded Q was 44 at 6 MHz compared to 53 for the AM receiver at 1 MHz. The integrator capacitor was changed to 0.005 µF and the transformer tap was changed to the 5 kΩ tap (BLU). In order to protect the gates of the MOSFET array, the V– and substrate diode connections were grounded and a 1N4152 silicon diode was placed from gate to ground. This diode does not participate in any detector action.

As with any crystal receiver, antenna matching is important to transfer as much power to the receiver as possible. I found that connecting the antenna to the eighth turn of the inductor was optimum. Substantial interference from local FM and TV stations can be greatly reduced by placing a 9 turn FT50-43 toroid in series with the antenna.

Make it Your Own

This article is intended to motivate experimentation in radio at the most fundamental level. If you build either of these sets, you will learn much about high-efficiency radio design and construction, and you will appreciate how the human ear can hear audio signals with energies much less than 1 µW. You will have to adapt the materials you have or can obtain. There is no joy in radio quite like listening to a radio where the only energy is being provided by the station itself, but you will have to cultivate the "art of listening." Hopefully, you can pass on this learning and joy to young people and help them catch the "radio bug." They may well become future hams and extend this wonderful hobby for some time to come.

I would like to thank Wes Hayward, W7ZOI, for valuable discussions during the development of these receivers.

Crystal Set Mobile

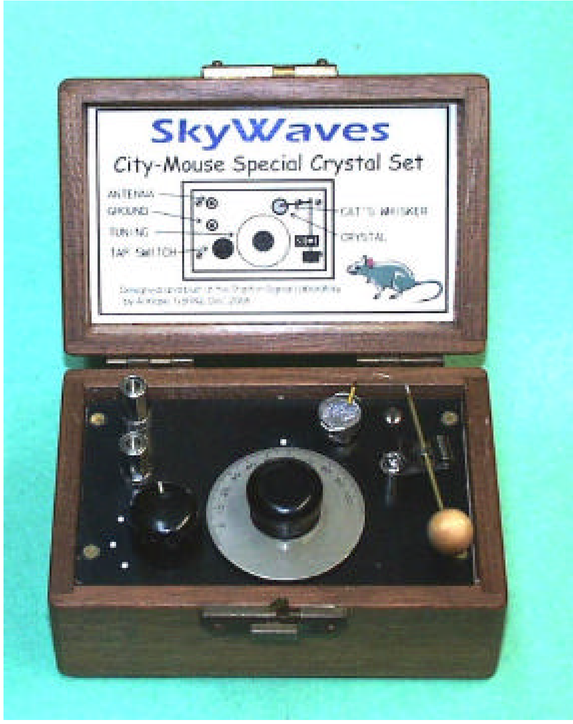
By Al Klase – N3FRQ – December 2006

Back in the 1990's there was a Yahoo Internet "club", devoted to crystal radio development called "The Ferrite Core." One of the perennial topics of conversation was the difference between operating a crystal set near high-power stations as opposed to a more rural setting. Someone, who had read Aesop's Fables likened this to "The City Mouse and the Country Mouse." The country mouse needed a sensitive radio hooked to a large antenna, but could faintly hear distant stations without a lot of interference. The city mouse's crystal set could drive a loudspeaker using only the bed springs for an antenna, but he couldn't hear much beyond the city limits.

I've spent most of my life as a country mouse, but recently I've been frequently finding myself in Jersey City. Indeed, crystal set operation is very different there. Short antennas work pretty well, and even my nearly-deaf rocket radio picks up multiple stations. It's even possible to operate a properly designed set with the antenna terminal connected to ground with the headphone cord and listener serving as the actual antenna.

I decide to apply what I learned down town to a couple of radios I was building as Christmas presents. The circuit is very similar to the NJARC Pretty-Good Crystal Set, but the coil is wound on a ferrite toroid to save space, and there are additional antenna taps on the "high end" of the coil to better accommodate short antennas.

I recently found myself in Maywood, near Hackensack, with some time to kill while Peggy rehearsed before a Sunday-afternoon concert. I took the city mouse for a walk in a nearby park. With 20 feet of wire, 5 feet in the air, and the ground wire clipped to a metal park bench, I could comfortably choose from five or six stations. I could still hear the Jets game on WABC, with just the ground connected to the antenna terminal.



Still having some time to waste, I picked up a four-foot stick as I returned to the car. I grounded the set to the ignition key, and extended the antenna wire out the sunroof with the stick. Sure enough, the Jets were still ahead. I wound the rest of the wire around the stick as a loading coil.

The ugly stick

After an enjoyable concert (The Four Seasons and a Brandenburg Concerto w/harpsichord), I listened to the crystal set down the turnpike through the Meadow Lands, past all the towers, all the way home. I think most were on night-time power by now, as none were obnoxiously loud. I need to try that again, in broad daylight, with a speaker.

THE CRYSTAL-SET RADIO

100 more Crystal Set plans

Everyone wants to make a RADIO.

The simplest radio is a **CRYSTAL SET**. (Sometimes called a **Crystal-Set Radio** or **Xtal Radio Set** or **Crystal Diode Radio**.)

However a **Crystal Set** needs a number of components that are very hard to get: (tuning capacitor with knob) and (crystal earpiece for $1.25).
The "air" TUNING CAPACITOR (20p to 415p) is not easily available and the postage is expensive. The germanium diode is a special component and the aerial coil wound on a ferrite slab is difficult to obtain.

But you don't need these components. They can be substituted.

There are hundreds of websites on the internet describing the **CRYSTAL SET** and if you want to build a "normal" set, you can Google these sites or 100 more Crystal Set plans. Many of them sell kits too.

But this article is different.

We are going to have all the fun of making a **CRYSTAL SET** but with modern components and easy-to-make components and with an amplifier stage. The output is loud so you don't need a long antenna. And we are going to make our own TUNING CAPACITOR and a very simple aerial coil (called a FRAME AERIAL) as well as replacements for the germanium diode (use a TRF radio IC or a transistor) and in place of hi-impedance headphones (use a piezo diaphragm) and a crystal earpiece equivalent (a piezo diaphragm).
It's even better to have one of each type of component so you can compare the performance, so no matter how many parts your get, nothing will be wasted.

We are also going to explain the fundaments of how the circuit works as even the simplest circuit has a number of very important features that are used in many other circuits.

But first we are going to learn about the components and how they combine to make the circuit work.
When two or more components are connected together they sometimes produce a completely different result to the capabilities of either item.
This is the case with a capacitor and inductor in parallel. An inductor is simply a coil - turns of wire on a cardboard tube - called a former and the centre of the coil is AIR. It is called an air-cored coil or air-cored inductor.
Each component (the coil and capacitor) is called a PASSIVE DEVICE - in other words it does not amplify, but when the are connected together they create a result very near to amplification. And they also produce a result of picking up a huge number of signals and only allowing one signal to appear across the pair. A truly amazing result.

We start by placing a capacitor across the coil.
There is so much activity in the air, from radio, TV, taxi and mobile phone usage that the air is filled with electromagnetic radiation.
This radiation will cut the turns of the inductor (the coil) and produce a microscopic voltage in the turns. This is enough to start the two components passing energy back and forth at a rate

determined by their values. This is the basis of our first discussion.
These two components are called a TUNED CIRCUIT and make up our first building block called THE FRONT END.
.

THE FRONT END

This consists of a coil and capacitor. These two components are in PARALLEL and the signal (called the RADIO SIGNAL or RADIO WAVE) passes through the centre of the coil and produces a voltage in the turns of the coil. The electromagnetic wave has to pass through the centre of the coil.
This voltage is the result of a mass of signals that are interfering with each other and producing a signal called BACKGROUND NOISE.
The voltage can be increased by an external aerial (called an ANTENNA) and it consists of ALL THE LOCAL radio stations (and everything else).
The voltage is a mass of signals and is absolutely useless as it represents all the stations AT THE SAME TIME.
However, across the coil is a capacitor and these signals charge the capacitor with the very small voltage produced by the energy of the signals. When the capacitor is charged, it delivers its voltage to the coil. The coil accepts the energy and converts it to magnetic flux.
After a very short period of time the capacitor becomes discharged and the magnetic flux collapses and produces a voltage in the coil of the opposite polarity to charge the capacitor again in the opposite direction.
These two components keep oscillating back and forth, using the tiny amount of energy from the stations.
There is a natural frequency for the capacitor and coil to pass energy back and forth and one of the stations will provide energy to assist this natural frequency.
When this happens, the amplitude of the signal increases and the signals from all the other stations cancel themselves out and only one signal (waveform) remains.
This signal is called the NATURAL FREQUENCY OF RESONANCE and it corresponds exactly to one of the radio stations.

The end result is a waveform that is the exact same frequency as one of the radio stations and when voice or music is played, the amplitude of the waveform increases and decreases. This will be the signal you hear in the earpiece or speaker.
It is called an AMPLITUDE MODULATED signal and that is where we get **AM RADIO** from.

Understanding the concept of a CAPACITOR and INDUCTOR in parallel is very important. They form a TUNED CIRCUIT that has a natural RESONANT FREQUENCY.
Here is a very similar analogy. You have a heavy metal ball on a long string attached to the gutter on your house - just like a pendulum. You can push the ball very lightly with a finger and after a number of pushes you will be able to get the heavy ball swinging in a very large arc.
The only way to keep it swinging is to push it very lightly at exactly the right time. If you push it at the wrong time it will eventually stop swinging.
The parallel tuned circuit is exactly like the ball. It wants to oscillate at a particular frequency.
All the radio stations are pushing and pulling the circuit at the wrong times and nothing is happening. But one radio station pushes at exactly the right time and the circuit starts to oscillate.
All the other stations are fighting each other just like one person pushing the ball sideways and another pushing the ball from the opposite side. The results cancel each other and you are the only one assisting the swing.
The TUNED CIRCUIT can also be called a FILTER with a very narrow BAND-PASS frequency but our simple explanation describes the operation much more clearly.

There are a few other terms used to describe the components in the font end:

LOOP STICK ANTENNA -This is an alternate name given to the coil of wire wound on a ferrite rod or slab. It also has the name ROD ANTENNA or FERRITE ROD ANTENNA.
The winding can be enamelled wire or flexible wire called LITZ WIRE. This is very fine strands of enamelled wire twisted together and covered in cotton. The purpose of changing a thick wire to lots of very thin wires is to prevent the radio signals creating loops of signals within the wire and these signals will cancel each other and not produce a signal out the end of the wire.
In our experiments, we have not noticed any difference in a coil made with ordinary enamelled wire and Litz wire.

Here is a set of components to make your own Crystal set from **Scott's Electronic Parts**:
You can see the rod antenna, germanium diode, crystal earpiece, capacitor and resistor. The kit costs about $9.00 plus postage and includes knob, clips and screws but no board to mount the parts.

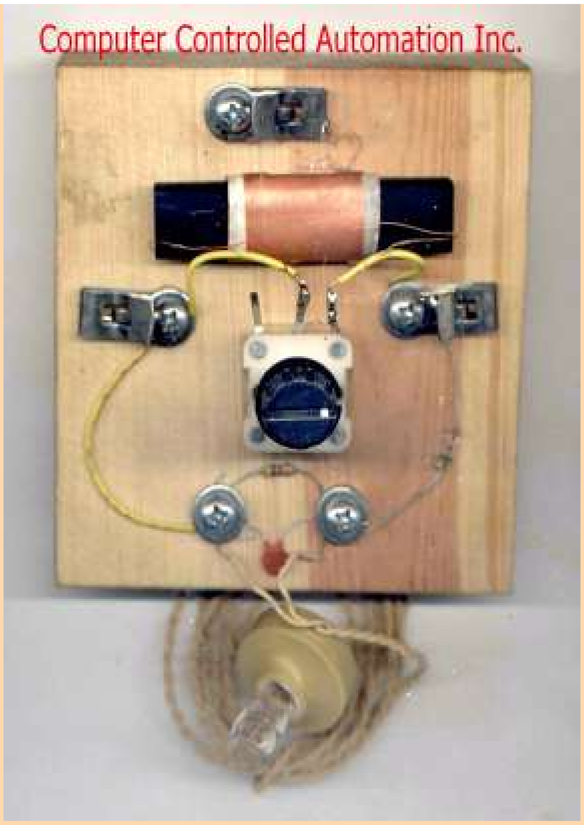
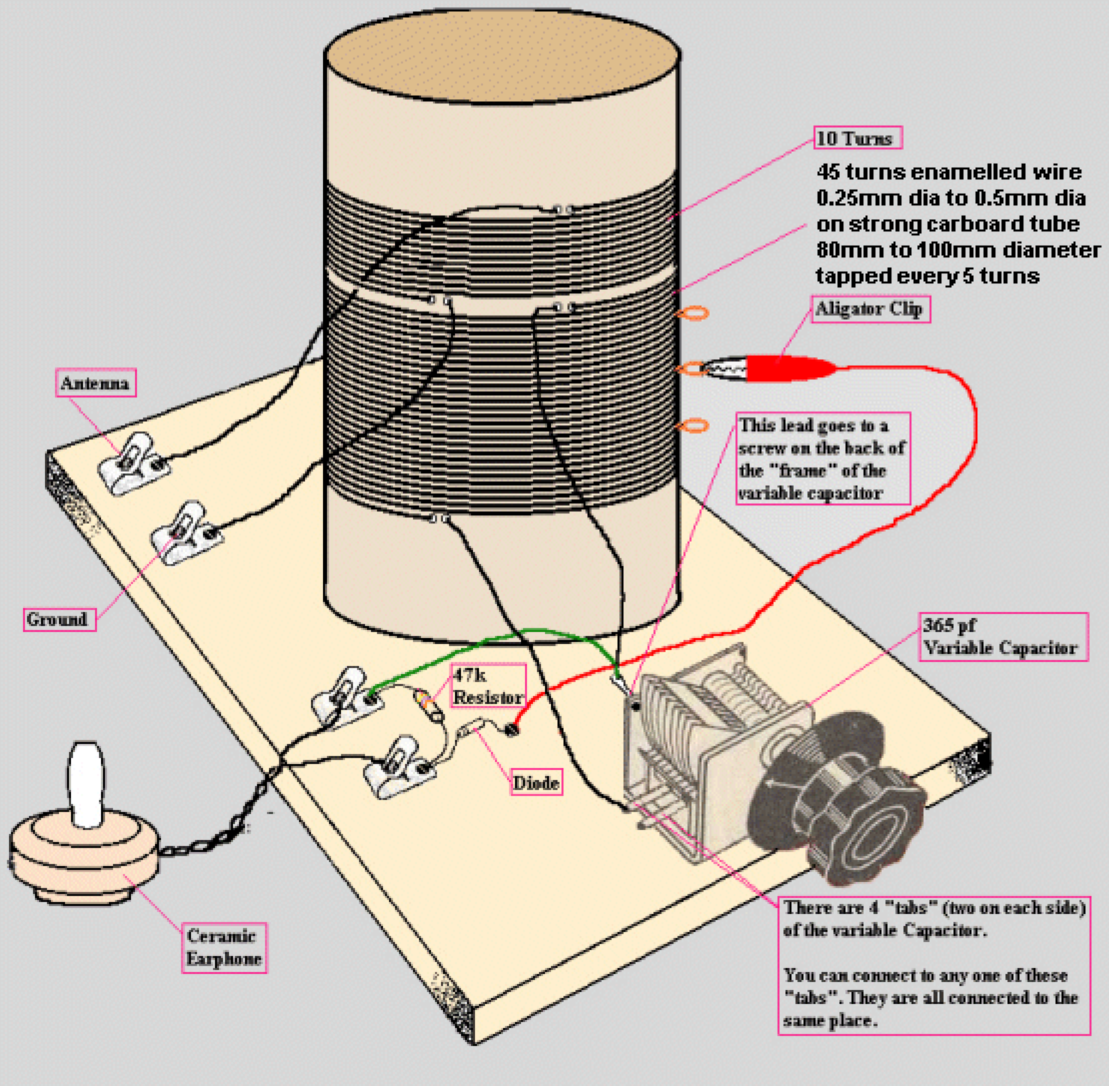
Ground
This is the FRONT END or TUNED CIRCUIT

Here are the components mounted on a board called BREADBOARD:



The top clip connects to a long antenna. The left clip connects to ground and the right clip connects to a short antenna.

Let me clear up a point. You do not need a ferrite rod antenna for the coil. You can use an ordinary coil wound on a cardboard tube and it will work just as well if you are using an outside antenna.
Here is the circuit using a home-made coil.



10 Turns
45 turns enamelled wire

Ground
365 pf
Variable Capacitor
47k
Resistor
Diode
Ceramic
Earphone
There are 4 "tabs" (two on each side) of the variable Capacitor.
You can connect to any one of these "tabs". They are all connected to the same place.

The tappings on the coil allow a wide band of radio stations to be tuned.
Each tapping allows a different portion of the band to be covered.

The next part to understand is this:
The coil and capacitor must not be LOADED. In other words, you cannot connect anything to this combination because the signal it is producing will be "taken away" or "removed" or "considerably reduced" by the item you are connecting to the circuit.
These two components are called a TUNED CIRCUIT and when they are not loaded they pick up all the radio stations, one station at a time, when the natural resonant frequency of the coil and capacitor exactly match the frequency of the radio station. The circuit actually "rejects" all the radio stations except one. Because all the other stations are trying to make the Tuned Circuit oscillate at a different frequency and it does not do this.
The result of the TUNED CIRCUIT oscillating under NO LOAD conditions produces a waveform that is very high and this gives the circuit GOOD SELECTIVITY. The circuit can select one station and reject nearby stations.
It also has good SENSITIVITY as it can pick up weak stations.
If you load the circuit, only the strongest signal will be detected and it will be spread across the full range of the tuning capacitor.
Obviously the theory is more-complex but we are explaining the end-result.
Theory talks about the "Q" value of the coil and this is its ability to produce a very good output when the magnetic flux collapses and the "Q" value increases when the circuit is not loaded. .
Although these voltages are very small (in the order of microvolts or millivolts) the result is very important as the rest of the circuit will be amplifying this waveform a few thousand times.
As we explained above, pushing the weight on a string only needs a push of 1 cm and eventually the weight will swing 1 metre. This is a gain of 100:1 The same thing happens with the tuned circuit. The incoming radio signal is in the order of microvolts, but the coil and capacitor will produce a signal as high as 500 millivolts. This is an improvement or "gain" of more than 1,000 and is referred to as the "Q" of the circuit.
You will also notice the TUNED CIRCUIT is not connected to any supply voltage. It does not have

be connected. It generates its own waveform from the signals in the air.
It should not have any DC current flowing through it via the supply as this would put a load on the circuit and reduce its operation.

However we must "pick-off" the signal so it can be amplified.
This must be done with a very high impedance circuit.

THE CONVERTER (detector) - THE DIODE

The next part of the circuit is the CONVERTER. Commonly called the DETECTOR.
It converts the RADIO FREQUENCY signal to an AUDIO FREQUENCY signal.
This is the job of the DIODE.
The radio frequency signal is a very high frequency signal (say one million cycles per second) and it is sending a tone of one thousand cycles per second through the air-waves.
What is happening is this: The one megahertz signal has a certain amplitude and over a range of the first one-thousand cycles, the amplitude gradually decreases and then increases again. If you look at the tops of this 1,000 cycles you will see a waveform that corresponds to the one kilo-Hertz signal.
The 1MHz signal is picked up by the coil and capacitor in the front end and makes it oscillate.
The radio frequency signal is gradually getting larger over 500 cycles then smaller over the next 500 cycles and this increase and decrease represents the 1,000 cycles per second tone.
This is the waveform (the signal) that passes through the diode. This will be explained further in a moment.
The diode does not pass any signals less than 200mV as the first 200mV is lost in the junction of the diode. This means the signals start to appear on the other end of the diode when they are above 200mV.

This is how the diode works:
Across the crystal earpiece is a capacitor. The capacitor gets charged via the diode.
The diode is present to stop the capacitor getting discharged when the waveform is in the wrong direction. (by this we mean - when the waveform is lower or smaller in amplitude than the voltage on the capacitor).
And the waveform is in the wrong direction about 50% of the time. To charge the capacitor for one-half-cycle requires 500 "little increments" in voltage with each increment adding a microscopic increase in voltage. We don't want this voltage to reduce when the waveform is reversing direction and the diode stops the voltage flowing back to the Tuned Circuit.
During the next half of the cycle when the pulses are getting smaller and smaller, the voltage on the capacitor is "bled off" by the load resistor.
The crystal earpiece detects this voltage. What we mean, is the diode allows the voltage to rise (increase) on the capacitor via lots of little "pulses" and the voltage increases in the form of a sinewave to a maximum amount. This voltage is passed to the crystal earpiece.
Once the voltage rises to a maximum, the little pulses of energy are not quite as strong, and the voltage on the capacitor reduces to form the second portion of the sinewave. This voltage is always being passed to the crystal earpiece and you can hear it as an audio signal.

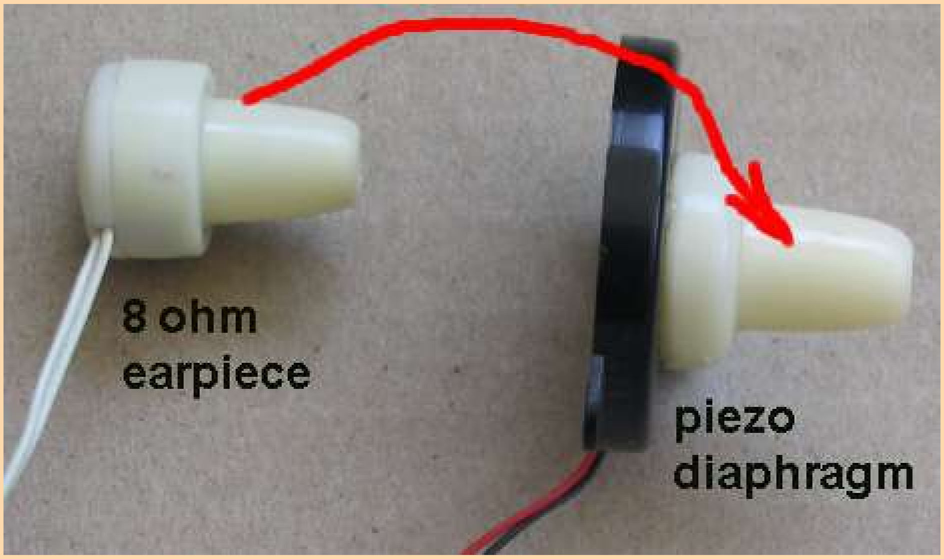
GERMANIUM OR SILICON DIODE

The preferred type of diode for a Crystal Set is germanium. This is because it drops only about 0.3v.
But a silicon diode can be used, even though it drops about 0.7v, if the radio stations are very loud (close by).
You have to remember, you need a very good aerial (and a water-pipe earth) to get any results with a Crystal Set because you are asking the signal to provide the energy to drive the earpiece.
By simply adding a transistor, you are improving the performance 100 times and the long antenna can be reduced to a FRAME ANTENNA and the earth can be the metal frame of your soldering iron.

THE EARPIECE or EARPHONE
also The Magnetic Earpiece or CRYSTAL EARPIECE

The earphone or earpiece used in a Crystal Set must be a high impedance device because the crystal set does not produce a high current and cannot drive a low-impedance earpiece. That's why a CRYSTAL EARPIECE is ideal.
It has a crystal glued to the back of the earpiece and connected to its top surface is an aluminium diaphragm. When the crystal expands and contracts as a result of a voltage applied via two electrodes, the diaphragm moves and you can hear the signal. It exhibits a very high impedance

because it consists of a crystal and no coil of wire is contained inside the case.
If you do not have a Crystal Earpiece, you can make your own from the shell of an 8 ohm earpiece and a piezo diaphragm. Only the front part of the earpiece is used.



Make your own Crystal Earpiece

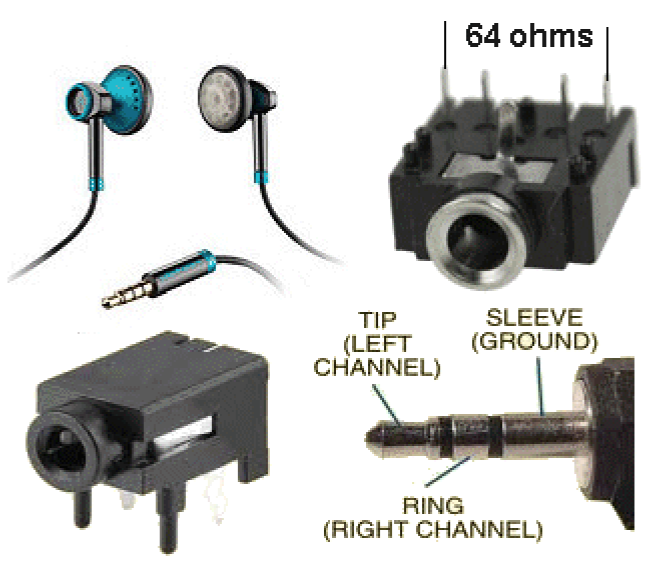
Hit the 8 ohm earpiece on the side and the front comes off. Glue the front onto a piezo diaphragm with hot-melt glue. See photo above.
The piezo diaphragm is a ceramic substrate that deflects in the presence of a voltage. It is quite sensitive and you can hear the audio quite clearly.
The waveform emerging from the diode in a Crystal Set is called AUDIO and although it has an amplitude of a few hundred millivolts, it does not have any current associated with it. The crystal earpiece and the piezo diaphragm react to this voltage.

THE 8ohm EARPIECE

The 8 ohm earpiece can be used with our 8ohm Buffer stage shown below.

16ohm 32 ohm and 64 ohm EARPIECE(s)

Earpieces and headsets from mobile phones are 16 ohm or 32 ohm per earpiece and are terminated via a stereo 2.5mm or 3.5mm plug. The earpieces are connected in SERIES to get the best coupling to our radio circuits and you need to find the two pins on a stereo socket to produce series connection. Get a multimeter and switch to "ohms." Try all the pins and you will get a click in the left ear then the right ear. Keep searching until you get a click in both earpieces at the same time. Use these two pins.



Stereo mobile phone headset - unusually 32R or 64R

PROBLEMS

The biggest problem with a Crystal Set is the need for a long antenna.
The first 200mV to 300mV of a signal is lost in the diode and you need a long antenna to pick up a signal so the output of the TUNED CIRCUIT has enough voltage to drive the high-impedance earpiece.
This requires an outside aerial 5 metres long and 3 metres high.
This is not practical for most hobbyists so we will be adding an amplifying stage to the crystal set so a shorter (smaller) aerial can be used.

THE FRAME AERIAL or FRAME ANTENNA or FRAME COIL

The aerial coil shown in the photo above is a ferrite slab with about 80 turns of Litz wire. You can find one of these in an old broken AM radio or from a parts-shop. In the instructions below we show how to make your own Ferrite Rod Antenna
An equally-good substitute is a frame antenna made by winding insulated wire in a rectangle around wooden sticks.

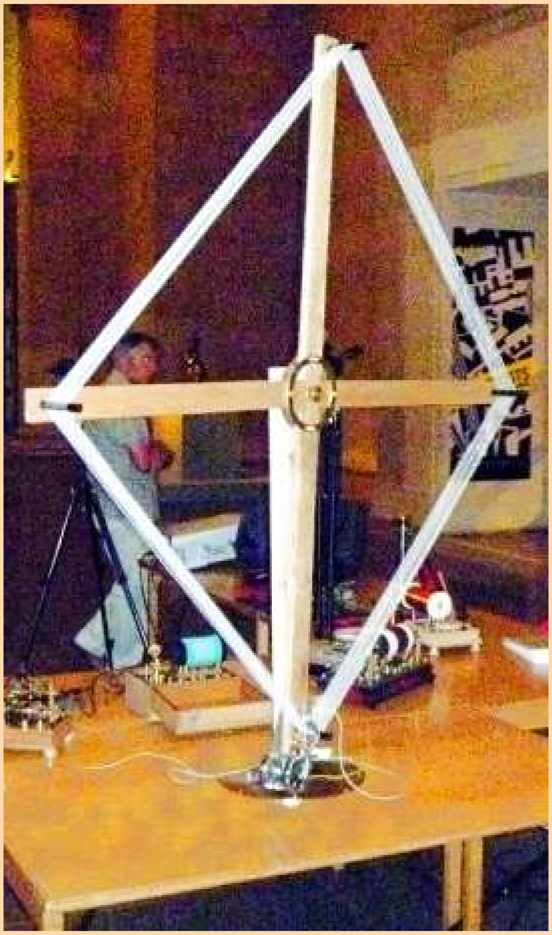
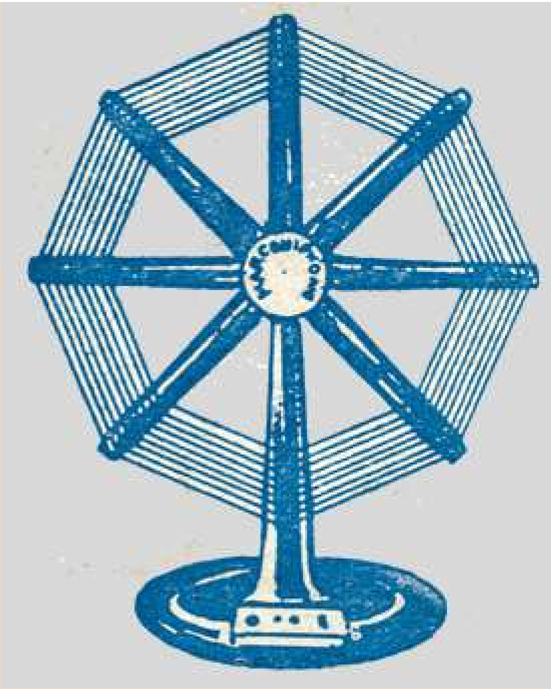
FRAME ANTENNA



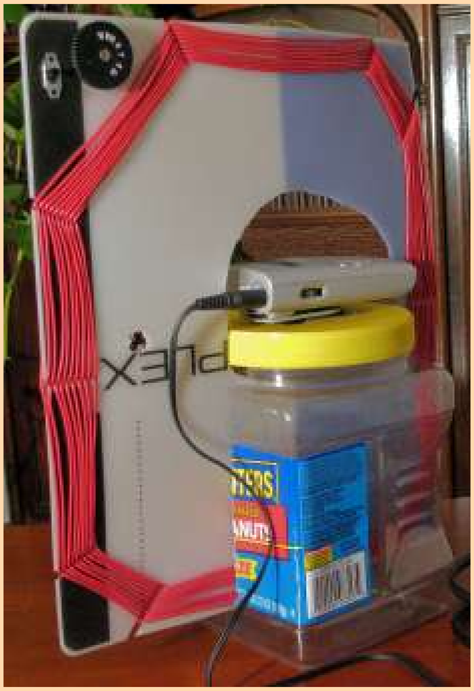
15 turns on a diamond frame

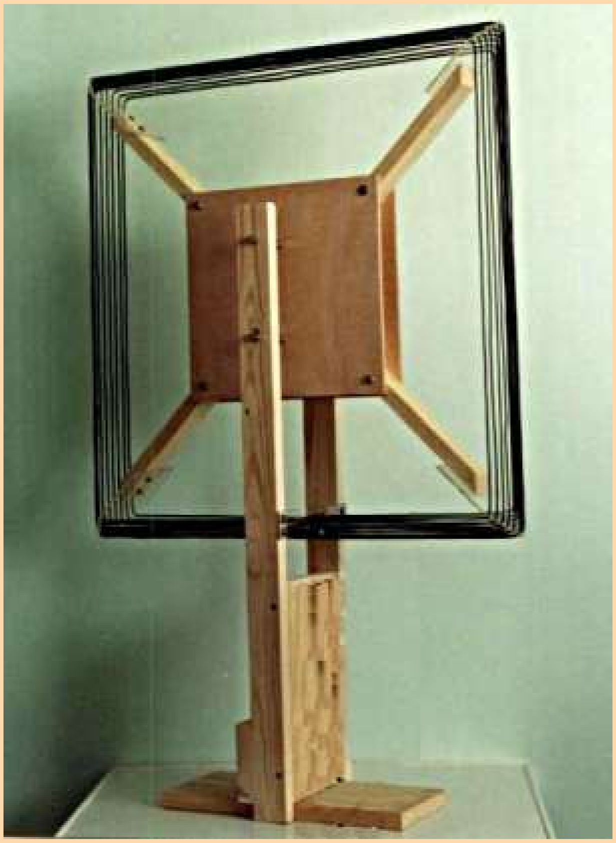


One of the earliest Frame Antennas

The Frame Aerial can be as large as 100cm x 100cm or as small as 10cm x 10cm around a plastic chocolate box.

Here are two FRAME ANTENNAS:





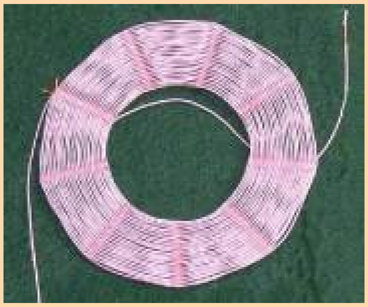
This will work just as good as a ferrite slab antenna. The slab antenna is just 100 times smaller. The slab antenna was invented so a transistor radio could be built in a small case. But if it is not available, you can wind 20 turns around a plastic chocolate box and it will work just as good.

Alternately you can wind 20 turns around a biscuit tin. Put a pencil on the tin and wind the turns over the pencil too. Remove the pencil and it will be easy to remove the turns. Use tape to keep the turns together.

The FRAME AERIAL does two things. It picks up the radio waves and it becomes the coil (called the INDUCTOR) in the TUNED CIRCUIT. It must be placed away from metal objects, such as a refrigerator.

BASKET WEAVE COIL

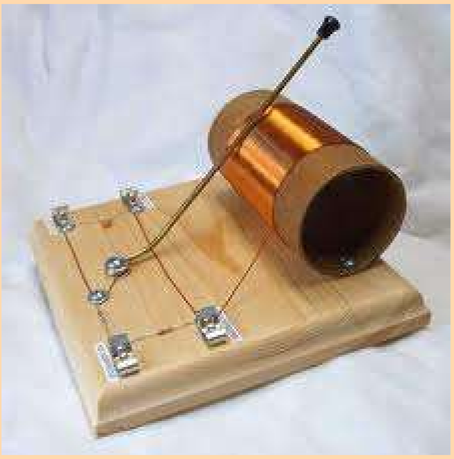
There is no point making a complex BASKET WEAVE COIL as it will not work any better than simply jumble winding all the turns at the maximum circumference of the coil, because the energy capturing capability of the coil relies entirely on the amount of flux lines passing through the centre of the coil.
By increasing the centre of the coil, the amount of flux is increased for the same coil size.
In fact, the simplest and cheapest is to wind turns around a box, as explained later in this article, or make a frame antenna as shown above. Technically speaking, a round coil has the best performance but only by a few percent.



A BASKET WEAVE COIL

THE VARIABLE INDUCTANCE TUNING COIL

Whenever the size or shape of the coil is changed, (or the number of turns), the natural frequency of the Tuned Circuit will change and a different radio station will be picked up.
This means tuning across the band can be done by altering the characteristics of the coil while keeping the value of the capacitor fixed.
Changing the inductance can be done in many different ways.
The coil can have taps every 5 turns and an alligator clips selects the correct tap. But very few radio stations will correspond exactly to each tap.
Another way is to have a slider move up and down the turns as shown in the following image:



The slider makes contact where the insulation has been removed. But it may touch two turns at the same time and create a "shorted turn" and reduce the "Q" of the coil.

Another way is to move a ferrite bar (rod) in and out of the coil:

THE SLUG TUNED COIL

To tune across the radio band, the natural frequency of oscillation of the TUNED CIRCUIT must be adjusted (changed). This can be done by changing the value of the capacitor or the value of the inductor.

The value of the inductor can be changed by adding or removing turns or changing the amount of magnetic material in the centre of the coil.
A ferrite bar can be screwed in and out of the coil or slid in and out and this component is called a **SLUG TUNED COIL**.
The following diagram shows a **SLUG TUNED CRYSTAL SET**:

A SLUG-TUNED RADIO

The circuit above is has a broad-band amplifier consisting of 10 transistors (IC1) and they are directly coupled (connected) to each other because it is not possible to "manufacture" a capacitor inside the IC. The IC has 3 terminals (pins, legs) and it looks like an ordinary transistor. Experimenting with this type of IC has shown that it is no better than 2 ordinary transistors connected in a direct-coupling arrangement.

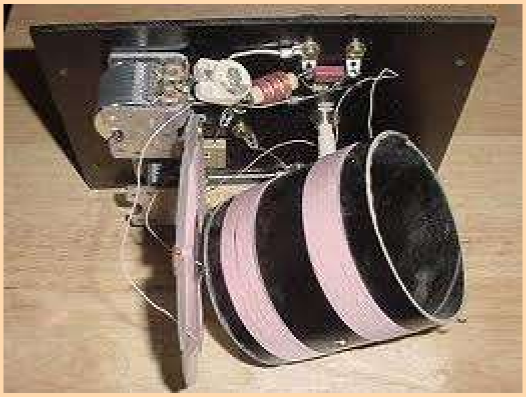
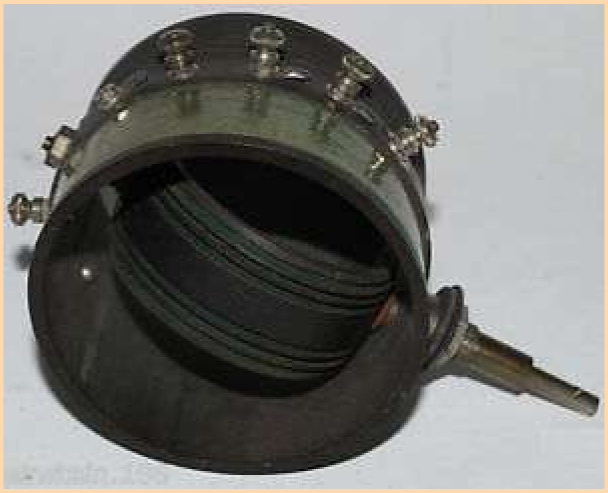
Here is the address of the site for the slug-tuned radio.
http://www.kristalradio.nl/
Unfortunately the site is in Dutch and the kit is not available. However the photos give a clear picture of the how the parts are connected.

The inductance of the coil can also be altered by winding another coil and placing it near the first coil so that the magnetic field interacts with each other and changes the inductance of the circuit. This is called a VARIABLE INDUCTANCE TUNING COIL.
You can have one coil inside the other, two coils near each other or two flat coils side-by-side. Any two coils will interact with each other.

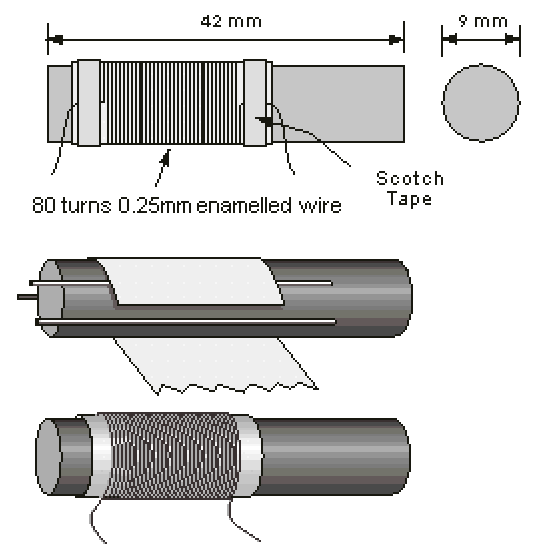




An Inductive TUNING COIL called a VARIOMETER

MAKING YOUR OWN FERRITE ROD ANTENNA

You can make your own FERRITE ROD ANTENNA by winding 60 to 80 turns of 0.25mm enamelled wire onto a 9mm ferrite rod or slab. If you wind it on a paper sleeve, you can move the coil along the rod to get the best performance. When the rod is slid out of the coil, the inductance changes considerably. However the inductance does change very slightly when the coil is moved along the rod.



Make your own ferrite antenna

Now we come to the tuning capacitor::

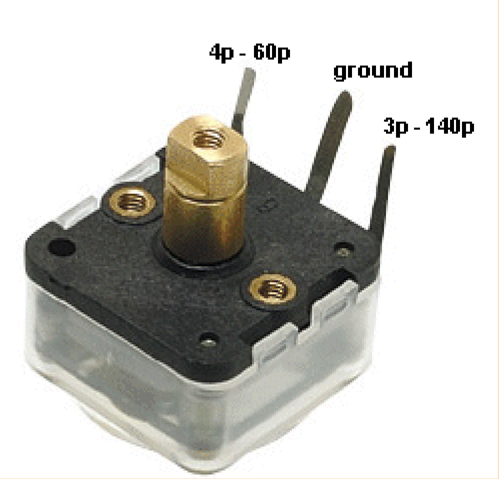
THE TUNING CAPACITOR

The "C" in the "LC" TUNED CIRCUIT can be fixed or variable. When it is variable, it is called a TUNING CAPACITOR. The sheets of aluminium in the air tuning capacitor below are called PLATES and the moving plates are called VANES. The fixed plates make up the STATOR.
The space between the plates is AIR. The photo shows a single capacitor. If two capacitors are connected to the same shaft it is called a GANGED CAPACITOR.
The plates do not come fully out of mesh and that's why the capacitor has a minimum value. The maximum capacitance is when the plates are fully meshed. The odd shape of the plates is designed to produce a fairly constant increase in capacitance as the plates are engaged.

An air tuning capacitor:

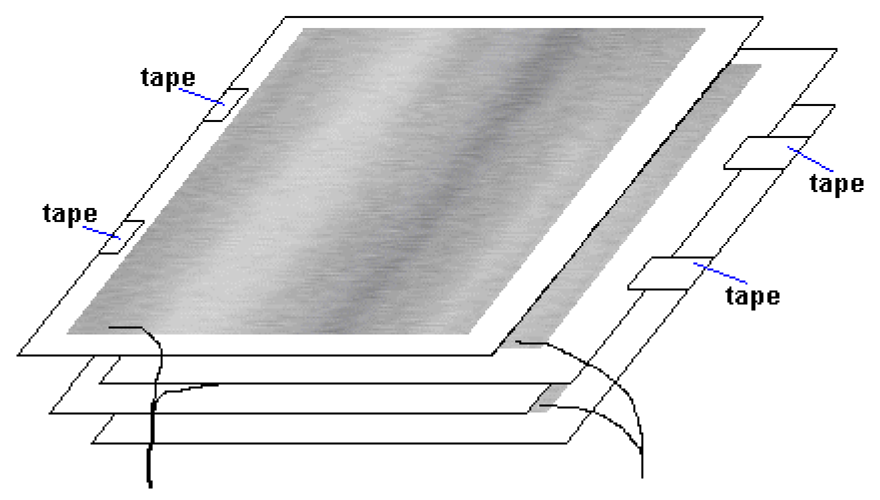
Air Tuning Capacitor
(Variable Capacitor)

The capacitor can be made much smaller by using thinner vanes and placing plastic between the vanes. Plastic increases the capacitance about 3 times to 10 times.



Tuning Capacitor as found in a pocket radio

The tuning capacitor can be replaced with a home-made equivalent that will work just the same.
You need:
4 sheets of aluminium foil (cooking foil) 10cm x 10cm.
4 sheets of thin cardboard 15cm x 20cm (cut A4 sheets in half).



HOME-MADE CAPACITOR

Tape a sheet of aluminium foil to each sheet of cardboard with sticky-tape around all 4 sides. Take one strand of wire from a length of hook-up flex and sticky-tape the end to each sheet of aluminium to make good contact. Place 2 sheets on top of each other and move the top sheet slightly to the left and sticky-tape the edge so they don't move. Do this with the other two sheets but move the top sheet to the right. Now interleave the sets. Connect the wire from the first sheet to the third sheet. Connect the wire from the second sheet to the fourth sheet.
The cardboard (or paper) between the aluminium sheets increases the capacitance three times.
The capacitance decreases when the sheets are moved apart and the capacitance increases when the sheets are moved in. The capacitance also INCREASES when the sheets are squashed together such as when a book is placed on them.
You can also make a smaller capacitor by making each sheet smaller and using 6 sheets. You can then add a 100p or 220p in parallel with the home-made capacitor, to select the lower part of the band.

EACH CIRCUIT

Each circuit we describe in the following set of circuits is an improvement or advancement on the previous. We also offer a number of different types of aerial coils, amplifying stages and earphones. Some of the circuits use easy-to-obtain components and home-made equivalents for hard-to-get items. There will be something in this section for everyone to build.

In all radio circuits you will encounter **TWO MAIN PROBLEMS**:

If the FRONT END (the Coil and Capacitor) is loaded too much by the "pick-off" of the amplifying stages, you will only get one station.
If you get squealing or "motor-boating," try a different circuit and layout as the components you are using, plus the voltage of the battery, will need changing.
You cannot always increase the voltage of the supply and get a louder output. Sometimes the increased voltage will stop the circuit working or it may introduce too much gain that the circuit starts to squeal.
The Radio IC (ZN414) DOES NOT WORK on a voltage above 1.5v and some of the transistor circuits completely stop working with a higher voltage. This has to do with the biasing arrangements and if the circuit is designed for a low voltage, you need to keep to the suggested voltage and experiment with a slight increase in voltage and see what happens.
Building a radio is not easy as the enormous amount of amplification of the combined stages creates a feedback loop via the power rail that sets the circuit into oscillation. This effect gets worse with a higher supply voltage and we will explain this further with each of the circuits.

MAKING A CRYSTAL SET

You can buy a **CRYSTAL SET** kit (see the photo of the kit, above) or the individual components (a kit is the cheapest) or use the replacement for the **FERRITE ANTENNA COIL** (16 turns to 20 turns on a 150mm biscuit tin) and/or the **TUNING CAPACITOR** made from aluminium foil and cardboard sheets.
You will need an outside antenna and an earth (such as a water tap or the frame of your soldering iron) to pick up the radio stations.
If you cannot put up an outside antenna, you will need to add one or more amplifying stages and this will allow you to reduce the length of the antenna and increase the volume of the audio.

ADDING AMPLIFYING STAGES TO A CRYSTAL SET

You can add two different types of amplifying stages to a crystal set.
You can connect amplifying stage(s) to the FRONT END and these will be designed to put less load on the front end so the sensitivity and selectivity increases. These stages work at the frequency of the radio signal and they are called RF STAGES (Radio Frequency Stages).
You can build these stages out of individual components or use a chip called a RADIO CHIP or RADIO IC (integrated circuit) for less than $2.00.
The chip contains 5 stages of amplification and these are RF stages (or RF AMPLIFYING STAGES) and the concept is called TRF. (Tuned Radio Frequency).
It is not easy to get this type of amplifier working because the stages produce a very high overall gain and you get a lot of "motor-boating" and squealing if the gain is not controlled. The gain must be reduced when a strong signal is being passed through the circuit because a strong signal will produce a large output and this will be so large that some of the waveform will find its way to the front of the amplifier via the power rail and start to be amplified again. To prevent the output getting too large, the circuit has a negative feedback line - called the AGC line - Automatic Gain Control.
It would be very difficult to reproduce these 5 stages of amplification with discreet components and that's why it is best to use an IC.

The next stage is a DIODE to convert the RF (Radio Frequency) to AF (Audio Frequency). This can be done with the diode-characteristics of a base-emitter junction in a transistor and we will show the alternatives.

Any stages after the diode are AUDIO STAGES or AUDIO AMPLIFIER STAGES.
The main job of the AUDIO AMPLIFIER is to increase the DRIVE CAPABILITY.
In other words, increase the current capability of the circuit for an 8 ohm speaker or 8ohm earpiece (or 16 or 32 ohm).
This is a very difficult thing to do and requires at least 2 stages.
The LOAD you can put on a Crystal Set must be 10,000 ohms or higher. (if you put a lower resistance (impedance) on the output, you will load the FRONT END and reduce its ability to separate the stations.
That's why a crystal earpiece is normally used with a crystal set. It puts almost NO LOAD on the circuit.
If you put a load on the circuit the result will be only one or two stations across the whole dial and only the most powerful station will be received.

If you don't have a crystal earpiece, you will have to use an 8 ohm earpiece. This will require an IMPEDANCE CONVERTING CIRCUIT of 1,250:1
This is a simple way of saying we want the 8 ohm earpiece to appear as 10,000 ohms to the

crystal set.
To produce an overall gain of 1250, we need two stages of amplification.
If a transistor has a gain of 70, it will it will produce an impedance conversion of 70 times. This is a realistic value. Transistors with a gain of 200 will have a gain of about 70 when fitted to a circuit.
This means the other transistor needs to have a gain of about 20 and that is easy to achieve.

ADDING AMPLIFYING STAGES TO THE FRONT OF A CRYSTAL SET

Adding stages to the front of a crystal set are called RF STAGES (Radio Frequency Stages) because they amplify the RADIO STATION SIGNAL.
It does not matter if you amplify RF signals or AF signals. The result is the same.
The only difference is this: The frequency of RF signals is much higher (1,000 times higher) and the coupling capacitors can be much smaller.
This allows an RF amplifier to be built into an IC - called a Radio Chip.
One of the most popular Radio IC's is ZN414 or YS414. This chip has been copied by other manufacturers as: MK484, TA7642 and LMF501T.
All the chips are the same but the pinout is different.
These chips work on a 1.5v supply and if the voltage is increased above 1.5v, the gain of the stages increases to a point of total distortion.
To prevent strong signals producing distortion on 1.5v supply, the output is passed back to the input via a 150k resistor. This feedback line is called the AGC (Automatic Gain Control).
The chip contains 5 stages of amplification plus a stage that converts the RF signal to AF (Detector Stage). This means the signal diode in a Crystal Set is not needed.

Here is the circuit of the TA7642 Radio Chip. It performs the same as the ZN414 Radio Chip.

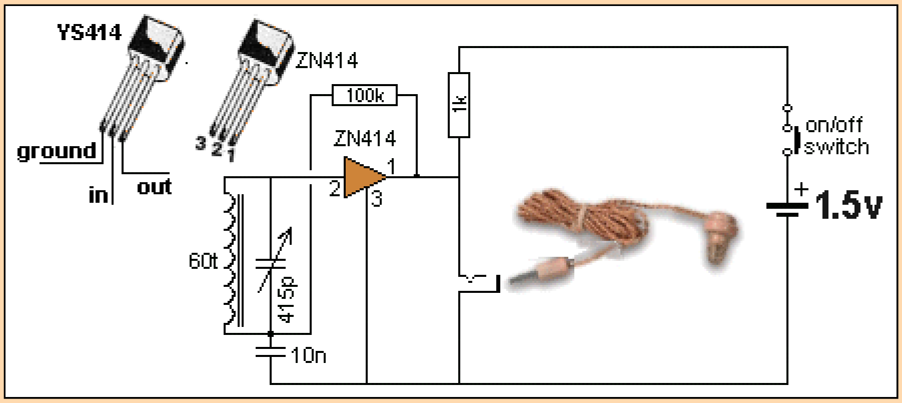
USING THE ZN414 RADIO IC

By using the ZN414 radio IC (or any if the equivalents) you can create a POCKET RADIO to drive a headphone or speaker.
But it is not easy to use the chip. The main problem is receiving the strong signals without producing distortion and then being able to pick up the weak stations.
A fixed 100k feedback resistor does not provide adequate control and a TRF radio has limited capabilities.
That's why radio manufacturers make SUPERHETRODYNE receivers. Even though they are more complex, the result is far superior.
However a simple TRF set can be made with the Radio IC and a few stages of audio amplification.

The following circuit uses just the Radio IC and a crystal earpiece or the home-made earpiece described above:
You can use a home-made FRAME ANTENNA or a home-made FERRITE ROD ANTENNA and a home-made VARIABLE CAPACITOR.



The Simplest ZN414 Radio

Connecting the ground (0v rail) to the frame of your soldering iron or a water tap will increase the output volume. The circuit above shows a Crystal Earpiece. Using a Crystal Earpiece may require adding a 10n across the earpiece to improve the output volume. The substitute Piezo Earpiece is effectively a 20n capacitor and an additional capacitor is not needed.

2 TRANSISTOR RADIO

Here is a simple 2-Transistor radio.
The secret to its performance is the 7 turn "pick-off" from the FRONT END (the TUNED CIRCUIT).
The ratio of 7 turns to 60 turns means a small percentage of the voltage generated in the tuned circuit is passed to the transistor. Thus it puts a small load on the TUNED CIRCUIT.
I don't want to go into any mathematics. The turns ratio is 60:7 = 8 but the effect of the 7 turns "pick-off" has an effect called the IMPEDANCE EFFECT and this is the SQUARE OF THE TURNS RATIO. Thus the IMPEDANCE EFFECT is 8 x 8 = 64. This means the "pick-off" (the LOADING EFFECT) is just a few percent. The front end can produce voltages as high as 500mV because a crystal set can produce a voltage high enough to pass through a diode (350mV) and have sufficient to drive a crystal earpiece.
Even though the front end has a "step-down" ratio, the voltage out the 7 turns will be sufficient to drive the first transistor.
The "transformer" does 2 things: It reduces the loading on the tuned circuit ENORMOUSLY and it produces an output with a higher current than is circuiting in the front end. Even though the transistor is turned ON and biased by the 33k, it is classified as a low-impedance load as far as the front end is concerned and the input signal has to be accompanied by a certain amount of current, otherwise the transistor will not respond to the voltage. The 7-turn "pick-off" is able to provide this current.
Both transistors are biased ON via the 33k base-bias resistors and thus the first transistor responds to the slightest millivolt signal.
This circuit was tested and had the same performance as the **Simplest ZN414 Radio Circuit** above. It can be operated on 1.5v to 6v and the strongest stations tend to overload on 6v. A short antenna is needed.

ADDING AN IMPEDANCE MATCHING STAGE

You can add an IMPEDANCE MATCHING STAGE to the output of the circuit above so a low-impedance earpiece can be used.
We call it an IMPEDANCE MATCHING STAGE because this is the correct technical term. It is an AMPLIFYING stage but it amplifies the CURRENT because the second transistor cannot drive an 8 ohm LOAD. 8 ohms is a very low resistance and if it is connected directly to the second transistor, the output will be almost zero.
The reason for this is covered in our discussion: The Transistor Amplifier.
This stage will not increase the volume but simply match the 8 ohm load to the circuit above.
It is very difficult to connect a LOAD to this type of circuit because it will take more current from the battery and cause the supply voltage to fluctuate. These fluctuations will be passed to the first stage and cause variations in the signal. This will be amplified by the first and second transistors in the form of a low-frequency buzzing called **MOTOR-BOATING**.
The only way to reduce or remove this noise is to add an electrolytic across the power rails and reduce the supply voltage. The third transistor simply takes the waveform on the output of the second transistor and delivers it to the earphone with a higher current. It is called an IMPEDANCE MATCHING STAGE as it effectively increases the 8 ohm load by a factor of about 100.

3-TRANSISTOR RADIO with buffer stage for 8 ohm earpiece

The 3rd transistor converts the 8R to about 800R

You can use 16 ohm, 32 ohm or 64 ohm in place of the 8R earpiece and these will give better performance as they will take less current and improve the stability of the circuit.
Low-impedance earphones create "motor-boating" due to the peaks of current and this can be very hard to fix.

A 2-TRANSISTOR RADIO with REGENERATION

The next stage in our discussion to get better performance is a feature called **REGENERATION**.
Regeneration sends a small output signal back to a previous stage in the form of POSITIVE FEEDBACK to INCREASE the original signal. The signal on the emitter of the first transistor is the same amplitude as the signal entering the base but the FRAME ANTENNA has a turns ratio of 5:15 and this increases the signal on the receiving section of the antenna by up to 3 times. But we want the returning signal to be just above the amplitude of the receiving signal and so a resistive adjustment (attenuator) is provided on the emitter to deliver just the right amplitude.
This has the effect of increasing the amplitude on the TUNED CIRCUIT and is just like reducing the load on the circuit.
As we have mentioned above, when the tuned circuit is lightly loaded, it will pick up a station at the exact frequency of transmission and if the dial is changed slightly, the station will disappear. This quality is called SELECTIVITY.
At the same time, the Tuned Circuit will pick up weak stations and this is called SENSITIVITY.
The quality of a receiver depends on the loading of the TUNED CIRCUIT.

Here is the original circuit from Elektor Magazine with the prototype made on matrix board and fixed to a base-board with a frame antenna made from two sticks of wood. The photo shows a speaker but the output is so low that you really need headphones.

2 TRANSISTOR REGENERATIVE RADIO from Elektor Magazine

The circuit is very complex and the output will be very low as the circuit cannot drive a low-impedance earphone via a 4k7 load resistor. The 4k7 resistor is actually driving the speaker (the transistor is simply discharging the 220u). The 4k7 only allows 32/4700 x 9 = 61mV to appear across the earphone - a very poor result.
The skill of designing a transistor stage is covered in our comprehensive eBook: The Transistor Amplifier and you wont make a mistake like this !!!
The circuit above can be simplified and we can add the REGENERATIVE feature to our **Simplest 2-Transistor Radio** circuit:

Our circuit uses a 15 turn circular FRAME ANTENNA 15cm diameter and a 5 turn REGENERATION coil.

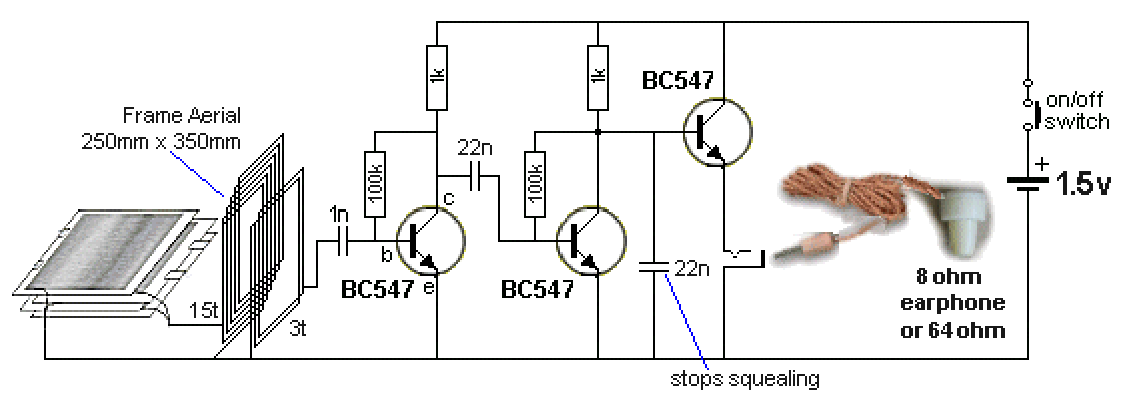
2 TRANSISTOR RADIO with REGENERATION

The regeneration coil is brought near the main coil and as it gets closer you can hear the audio get louder. If this does not happen, turn the coil around.
Early radios used this technique and the operator had to adjust the coil by hand. No-one minded because radio was a fascination and the simplest radio cost more than a weeks wages. To listen

to a broadcast through headphones was an amazement and listeners would sit all night with headphones listening to music.
This is very fiddly and by adding an extra buffer stage, we can use a Frame Antenna with a very clever "pick-off" that does not load the front end. This gives the circuit very good sensitivity and selectivity without regeneration.

3 TRANSISTOR RADIO

Here is our final design for the simplest self-contained 3-Transistor Radio using our home-made Tuning Capacitor and 250mm x 350mm Frame Antenna. It picks up the local stations and drives a low-impedance earphone or set of earphones (from a mobile phone).



3-TRANSISTOR RADIO

The circuit performs very well and uses readily-available components. The 22n across the output is essential to stop squealing.
The secret to sensitivity and selectivity is the turns-ratio on the Frame Antenna. The 3-turn "pick-off" puts very little load on the front end and this allows the stations to be tuned with our home-made Tuning Capacitor.
The circuit contains all the features we have discussed above and only needs a 1.5v supply.
Build this circuit before you buy any expensive tuning capacitors, IC's or ferrite slab antennas as you will not get any better results.
This is called a TRF circuit and because the stages operate at Radio Frequency or Audio Frequency. Due to the high amount of amplification, the circuit can start to squeal (feedback, motorboat) due to the layout.
You may need to shorten or lengthen the leads or move the parts slightly - it's that critical.
However the result is a portable radio that needs no earth and will pick up the strong stations.
You can try connecting the 0v rail to the metal part of a soldering iron to increase the number of stations.

LOADING

The whole success of picking up a radio station is the RECEIVING CIRCUIT. The receiving circuit is the coil and the signal in the air (from the radio station) must go down the centre of the coil.
It cannot pass over the top or the bottom of the coil. Only the signal that goes down the centre of the coil is received.
As you can see, the centre of the coil is not very big and it is amazing that the signal can pass down the centre. But it does, and that is the only signal that will be amplified.
This signal is passed to the capacitor and we have explained how the signal is gradually increased and increased in amplitude until it is as large as 500mV. The signal from the radio station may be as small as a few millivolts, but as it keeps pushing the "swing" back and forth, the amplitude get larger and larger.
If you put your finger on the "swing" you will prevent it get larger and larger and it only requires the slightest touch of your finger to prevent the swing gaining full amplitude.
In electronic terms, your finger is called LOADING THE CIRCUIT and since we have to pass the signal to further stages of amplification, we need to "tap" or "load" or "pick-off" a signal.
The aim is to load the circuit as least as possible because the actual energy entering the circuit is very small.
In fact, this is all the energy we can remove as that is all the energy entering it.
Because a very small amount of energy is entering the "front-end" we classify it having a very

high impedance. It is very difficult to provide a value of impedance for this circuit because impedance has the term "Z" and the circuit is operating a very high frequency so resistance values are not the same as impedance values.

The actual resistance of the circuit is ONE OHM but the impedance is more like 10,000 ohms to 100,000 ohms.

We can explain its high impedance if we put a 100,000 ohm resistor across the circuit. The waveform will be reduced very slightly. If we put a 10,000 ohm resistor across the circuit, the signal will be reduced a reasonably large amount. If we put 1,000 ohms across the circuit it will stop working.

This means a load of 100,000 ohms will have the least effect.

In a crystal set, the diode creates NO LOAD until a voltage of 350mV is reached. It then passes excess voltage to a crystal earpiece that has a very high impedance. That's why a crystal set will produce a good output. The LOADING is very small.

When a transistor is connected to the TUNED CIRCUIT, it starts to put a load on the circuit after 600mV and this load is VERY HIGH. The "resistance" of the base-emitter junction is about 1k and the signal will find it very difficult to rise above 600mV because the incoming energy is not sufficient to increase the voltage.

Adding a capacitor between the base and the front end allows the transistor to be self-biased and get a turn-on voltage of about 600mV from a base-bias resistor.

The FRONT END is now separated from the transistor and ANY voltage it is producing will be passed to the transistor via the capacitor.

Whereas, with the crystal set, the first 350mV could be produced without any loading, the circuit is now loaded AT ALL TIMES.

This means we have to load the circuit as lightly as possible to be able to pick up individual stations.

The only way we can do this is to use a capacitor of the smallest practical value and this has to be worked out by trying different values. If the value is too small, the transistor will not detect a small signal. If the value is too large, the circuit will stop working.

Values such as 1n, 10n and 100n are suitable.

Values such as 1u, or 10u will be too large.

The CRYSTAL SET loading and a transistor load are completely different.

The transistor loads the front end ALL THE TIME and that's why you need to use a transformer or other ways to reduce the loading. Sometimes a Field Effect Transistor is used as it puts almost no load on the front end.

CRYSTAL RADIOS AK (/)

Crystal Set with Output Meter

I felt that it was not easy to evaluate sensitivity or level of output of a crystal set because human ears are not objective enough. There are several articles on the net about showing the output level as voltage or current. If you connect a voltmeter at the phone jack, the input impedance of the meter will affect the balance between the set's output impedance and the phones input impedance.

I found Mr. Billy Cheung in Hong Kong published an article about a crystal set with an output indicator (http://theradioboard.com/rb/viewtopic.php?f=2&t=6082). (http://theradioboard.com/rb/viewtopic.php?t=6082) It also seemed very nice set to build, so I did. I bought a DC current meter with -50 to +50 uA range at AliExpress. At that time it was the only model available. Since the meter is large, 10cm x 8cm, the case needs to be fairly big, 21cm x 10cm x 7cm.

There are three modifications (additions) to the original. I added a switch to make one of two gang variable capacitor, C1, a part of the tank circuit or an antenna impedance matching capacitor. A switch was added to increase the number of turns for the regeneration in case of MOSFET detection. The last change was to add a switch to increase capacitance of C2 by adding the second section of the air variable capacitor.

Because the case was large, wiring was easy. Therefore, it did not take so long to build the set, except making a few corrections on my stupid wiring errors, as usual.

Performance:

My antenna is about 12 m long wire hanging in my garden, and the ground is a 50 cm copper bar buried in the garden soil. In mode 1, sensitivity is good. We have three local stations, JOPK, JOPB, and JOVR, transmitted at 12 - 16 km distance with 10 kW power. After fine tuning, following values for output in uA were obtained. The values did not change by using different phones or amplifiers.

	1N60	3DQ
JOPK	6.3	8.5
JOPB	3.8	4.5
JOVR	3.8	5.0

Human feeling of loudness for JOPK cannot find any difference between the two detectors. I have no idea if the numbers above are high or low in my environment. No other stations were heard. Because of the capacitor layout in the output circuit, the output sound does not include high audio frequencies and, therefore, is soft, although I have not checked the frequency distribution.

Selectivity of 3DQ is good, while 1N60 gives broad tuning. However, this difference may not be caused by the detectors but by the circuit difference. In case of the diode, primary tank circuit has no tap, and the FET's source gets the signal from the tap.

In mode 2, over-all performance is not satisfactory. Sensitivity is not quite as good as mode 1, and selectivity is even worse. If you set the taps near the top (tap #2-4), you can hear several SW stations in China and Korea as well as domestic ones, but they can be picked up everywhere on the dial. Therefore, there is no way to know the frequency which the set is tuned. This may be caused by the unused part of the coils, lowering the Q, as Mr. Broesel pointed out in the original post by Mr. Cheung (http://theradioboard.com/rb/viewtopic.php?t=6082).

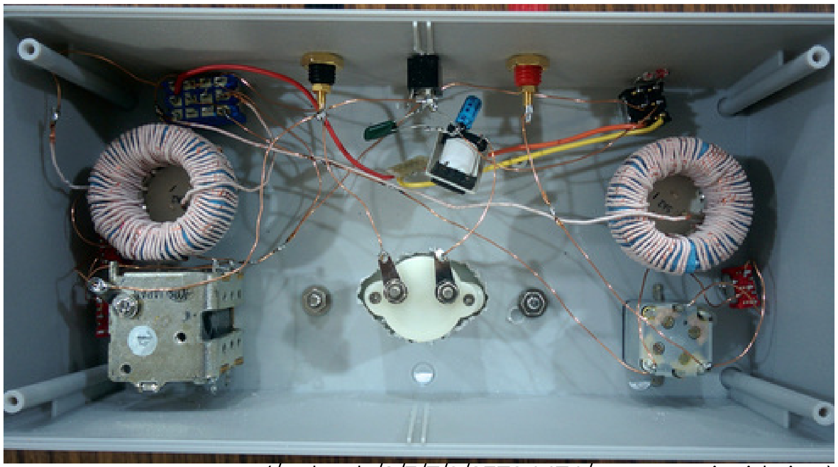
Face of the set

The case is TAKACHI TW11-8-22G, W110 x D220 x H75.3mm. You can tell how large the meter is.
I put the rotary switches for tap selection upside-down by mistake, so selecting the taps is confusing a little.



(/uploads/8/3/7/9/83794474/cs_meter_inside.jpg)

Inside

Since few parts were used except switches and variable capacitors, inside the case is almost vacant. The DP4T toggle switch was the most expensive among connectors and switches.
The 3DQ is hidden behind the small universal board, while the 1N60 is connected to the terminals of the switch.

CRYSTAL RADIOS AK (/)

Crystal Set with Q Multiplier

I found a very interesting YouTube video, showing an application of a Q multiplier to a crystal radio.

The base set is the one published by Mr. (http://www.geojohn.org/Radios/MyRadios/CRKit/CrystalKit.html)John Fuhring (http://www.geojohn.org/Radios/MyRadios/CRKit/CrystalKit.html). It uses two toroidal cores for antenna tuning and station tuning. Linking the two toroids are done by few turns of coupling coils on both of the cores. I used the same cores (T80-15 (http://www.amidoncorp.com/t80-15/)) as in the original article. The linking coils are wound by 24 AWG wire, connected to a 100 ohm variable resistor which attenuate the signal to the secondary coil.

I used 40/60 litz wires for the tuning coils, which was suggested in the Fuhring's article. Another difference between the original and mine is to have an additional tap for the Q multiplier.

The Q multiplier I used was shown in the video by Mr. VK3YE in YouTube (https://www.youtube.com/watch?v=4ix5gNrJy2E). Capacitance between the hot end of the tank circuit and the base of transistor is critical. If it is too large, say 100 pF, it rings all the time. If it is too small, it does not work. At first, I twisted the wire from Q1 to the one from C2, as suggested in the video, the connection was too weak. So, I twisted the two wires as shown in the photo. My guess of the capacitance is about 15 pF.

Performance of the base set is not bad, but not great. There must be many possible reasons that mine may not be as good as the original, although I cannot think of any. The sensitivity is a little less than the Loose Coupler set (LC). The selectivity is as good as the LS, but this set requires no special tuning procedure, which is needed in tuning with the LC. I could listen three local stations very well, but no other stations could be heard even at night with an audio amplifier connected to the output.

With the Q multiplier ON, the sensitivity increased dramatically. Several stations in Tokyo (200 km away) could be heard after tuning with patience. The variable capacitor, especially the secondary for station tuning, needs to be adjusted very little by little, and it also changes its capacitance with my hand. If I assemble the set again, I would 1) use air variable capacitors, instead of poly film ones, 2) add vernier drive mechanism to the secondary variable capacitor, and/or 3) add a variable capacitor with a small capacitance, e. g. 10-20 pF, parallel to C2 for final adjustment.

Fortunately, I have an old SONY ICF-7600D (http://stephan.win31.de/sony76-4.htm) BCL radio, so I used it for making its tuning very easy for specific stations. First, set the receiving frequency of ICF-7600D to the frequency of the station you want to listen and leave it on. Then rotate the tuning dial of the set and find the point which causes the oscillation noise on the 7600D. This means that the set is tuned at the same frequency as the 7600D is receiving, which is digitally displayed on it. Remaining work is not so difficult if the signal is strong enough. Final tuning should make the station audible. I have received 5 stations with 50-100 kW power within the 300 km range in addition to the local ones. FYI: Transmitting power of radio stations in Japan is not as strong as other countries, in general.

Selectivity of the set becomes very sharp with Q multiplier, but since there are no overwhelming stations in my area, I have no trouble separating stations without it.

Playing with this machine is fun, but without Q multiplier, there is not much left to do. With the Q multiplier, it is exciting to listen distant stations, but I feel guilty for using it, because, although it is not directly amplifying the signal like regenerative radio, it is still with a help from a battery.

August 15, 2016

On the night of September 29, 2016, the following stations were caught when Q multiplier was ON. All stations were listened through an audio amplifier.

Frequency, kHz	Call sign	Location
639	JOPB	Shizuoka
711	HLKA	Incheon, Korea
747	JOIB	Sapporo
774	JOUB	Akita w/QRM
810	AFN	Wako w/QRM
828	JOBB	Osaka
846	JOCP	Koriyama
882	JOPK	Shizuoka
954	JOKR	Tokyo
972	HLCA	Danging, Korea
1008	JONR	Osaka
1089	JOHB	Sendai
1134	JOQR	Tokyo
1170	HLSR	Gimje, Korea
1242	JOLF	Tokyo
1314	JOUF	Osaka
1404	JOVR	Shizuoka
1566	KLAZ	Jeju, Korea

All stations are in Japan except those in Korea.

It seems sensitivity of the set is not good when frequency is below 700 kHz. No stations near 1400 kHz were heard because of the strong signal at 1404 kHz.

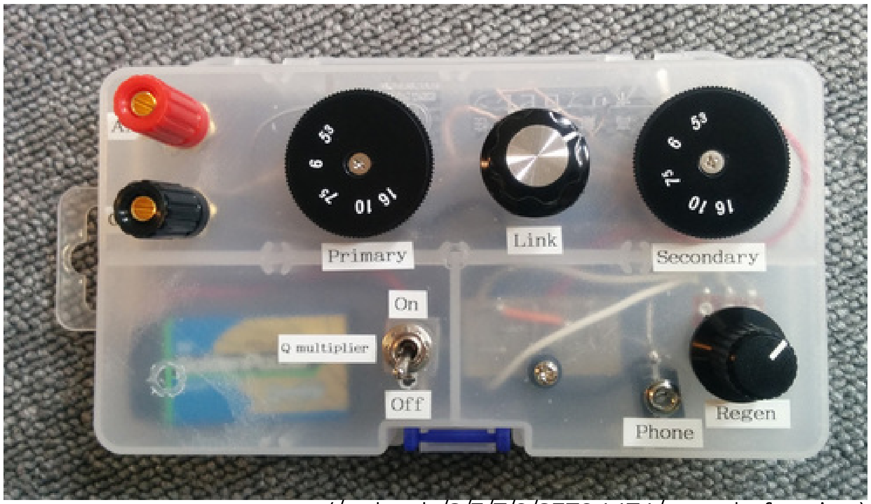
©Atsushi Kano 2016/08

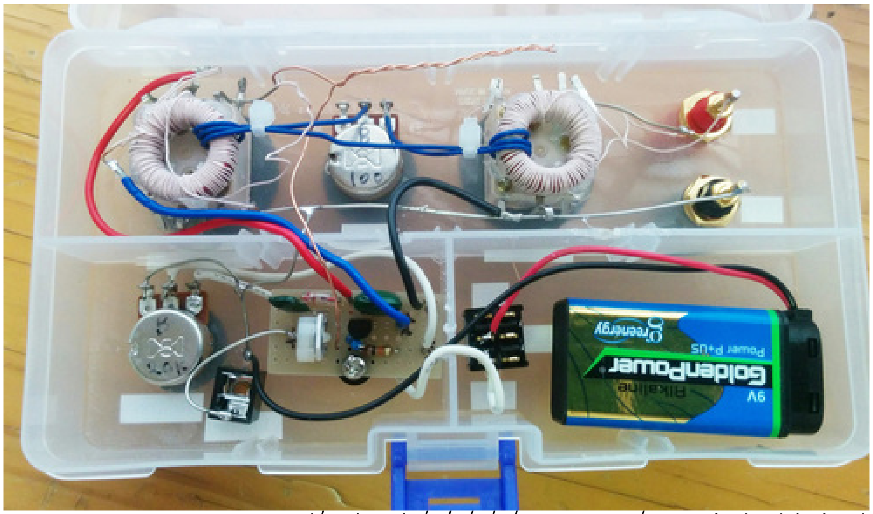


(/uploads/8/3/7/9/83794474/q_mult_face.jpg)

Face of the set

I used a small plastic tackle box sold at 100 yen (about US$1.00).

Top half is the crystal set designed by Mr. John Fuhring and right bottom is the Q multiplier . As I mentioned in the above, it is not easy to tune faint stations because my hand effects on the tuning while it is on the dial.



(/uploads/8/3/7/9/83794474/q_mult_inside.jpg)

Inside

I put all the parts for Q multiplier, the detecting diode, and few other parts for the crystal set on a small universal electronic board. The trimmer potentiometer, R5, was set to about 40 k after a few adjustments. Coils are hot-glued to the back of variable capacitors.

You can see the twisted wires, C3, for coupling signal from L4 to the base of Q1. The thinner blue wire forms L2 and L3. Originally it was a litz wire, but the link was too strong, so I changed it to the ordinary AWG 22 wire.

CRYSTAL SETS PART 1 - INTRODUCTION

What They Are, Why They Came Into Being and How YOU Can Build Your Own CRYSTAL SET!

What are Crystal Sets? I am glad you asked! It is a fascinating subject dating back to 1920 when Marconi first started experimenting with radio broadcasting from his station 2MT in Chelmsford.

The earliest listeners to Marconi's experimental radio programmes would have mainly used the most basic of radio sets called a Crystal Set. Companies such as the W.G Pye began producing early radio sets in 1921 which used electronic components called 'valves', the forerunner to today's transistors and silicon chips). These glass valves could be arranged to amplify the weak radio signal to make them louder - enough to operate a loudspeaker. However these radios were expensive and needed electricity or bulky lead acid batteries to operate.

THE MAGIC OF A CRYSTAL SET

The crystal set was popular during the 1920's and 30's because it was cheap to buy, much cheaper if you built one yourself, perhaps only a few shillings. Additionally a Crystal Set did not require electricity or expensive batteries, however it could only provide enough volume for headphone listening, and if it was situated in an area of low signal strength the listener would also require a very quiet room as the volume would be low. However In the 1920's hearing voices and music from a station miles away with no wires (hence the term Wireless) really was a magical experience! Listeners in the early twenties were also tinkerers and experimenters, trying different designs of crystal set in an attempt to get the loudest and clearest reception.

Since crystal sets have no batteries and no mains power, they rely entirely from the electrical energy developed between the aerial an earth connections - producing sounds as if by magic.

The crystal set had to be carefully tuned into the station by making adjustments to a tuning coil and condenser, these early crystal sets had the added complication of using a 'Cats Whisker' as the detector. The detector converted the radio waves received from the radio station into an audio wave that could be heard in the headphones. The Cats Whisker was a fine wire that rested onto a piece of galena, the crystal, and had to be very finely adjusted to obtain the loudest and clearest sound. Once the 'sweet spot' was found it was important not to move it, it would be very frustrating if someone bumped into the table and dislodged it!

To work at all a crystal set requires a very large aerial, but this is nothing more than a long piece of wire, perhaps 20 to 50 yards of insulated copper wire, hung outside around a garden between poles or trees, or even around the loft space. For the aerial to be effective it needs to be balanced with an earth. An earth is simply a copper rod or pipe about one yard long driven into some soft damp earth with a mallet. At the top of the pipe is fitted a jubilee or hose-clip to which is attached a length of insulated copper wire which is then fed into the house, along with the aerial wire, to the room where the crystal set will be operated and connected to the set's terminals.

It is quite possible to build your own crystal set. In its very simplest early form a crystal set consisted of a coil of wire, something called a 'detector' and a pair of very special headphones.

The coil of wire is called a Tuning Coil, and the number of turns of wire on the coil determines the wavelength (frequency) that the set is tuned into. Tuning to different stations can be accomplished by varying the number of turms on the coil, or more easily by having many different tapping points on the coil so that adjustments can be made.

To make tuning easier a component called a tuning capacitor can be included in the circuit. In very early sets a tuning capacitor was not always included to keep costs down, or due to their being difficult to obtain.

The Detector converts the radio wave received into an electrical wave that is suitable for the headphones to, in turn, convert into sound waves that can be heard by the human ear. In the very early days of the crystal set the detector consisted of a holder containing a piece of galena crystal that had a very thin and springy wire placed on its surface that had to be very delicately adjusted to find the sweet spot where the radio station could be heard. This was commonly referred to as a "Cat's Whisker". Modern detectors are called diodes and are more efficient than early detectors and cats whiskers. Diodes are still quite readily available and inexpensive. Part numbers for modern diodes include OA90, OA91 and IN34. Diode part numbers that are perhaps now more difficult to obtain include OA47 and OA81.

The headphones have to be of a very special type called high impedance headphones. Because there is no additional power source in a crystal set the current generated in the circuit is tiny - minuscule in fact. Ordinary low impedance headphones, such as Walkman headphones, would present a virtual short circuit to the crystal set allowing the tiny signals to drain away to earth & consequently producing no sound - not very useful!

High impedance headphones, on the other hand, reduce or impede the flow of current down to earth, in effect saving the tiny signals to produce sounds from the headphones that we can then hear.

There is a problem however, these high impedance headphones that were so readily available in the 1920's and 1930's are to so easy to obtain today, but some specialist vintage radio outlets still stock them though the price can be quite high. They can still be seen in museums of course. All is not lost though, today we can obtain a special earphone called, appropriately, a crystal earpiece very easily and far more cheaply than. An electronic component, called a resistor, must be connected accross the crystal earphone to allow a path for DC current to get to earth. The value of the resistor is usually 47,000 Ohms and without it a crystal earphone tends to block DC current and as a consequence the sound will be very quiet and distorted.

Aerial and Earth: For a crystal set work it needs an efficient aerial and earth. Since a crystal radio has no power - no batteries or mains electricity - it relies entirely on the radio wave energy sent out from the radio station's transmitter and collected by the aerial to work. The aerial simply consists of a length of wire, but it necessarily has to be quite long, usually in the order of 10 to 20 meters. For the aerial to be effective the crystal radio set also has to be connected to a good earth point. A good earth often consists of a 3 or 4 foot copper stake driven into the ground, but sometimes a water pipe can be used to reasonable effect. (Safety: Never use the earth pin of a household mains plug)

The circuit diagram (schematic) for a crystal set is shown below. Practical designs are shown on the following pages.

No AM radio stations or transmitters in your locality or country?

Has your local medium wave broadcast station closed or been moved to VHF/FM or Digital? Don't worry! You can still build and experiment with crystal sets and TRF radios by also building or buying a simple low power AM transmitter. So, not only can you use your crystal sets but you can also run your own radio station that can be heard in and around your home - playing the music or programmes that you want to hear!

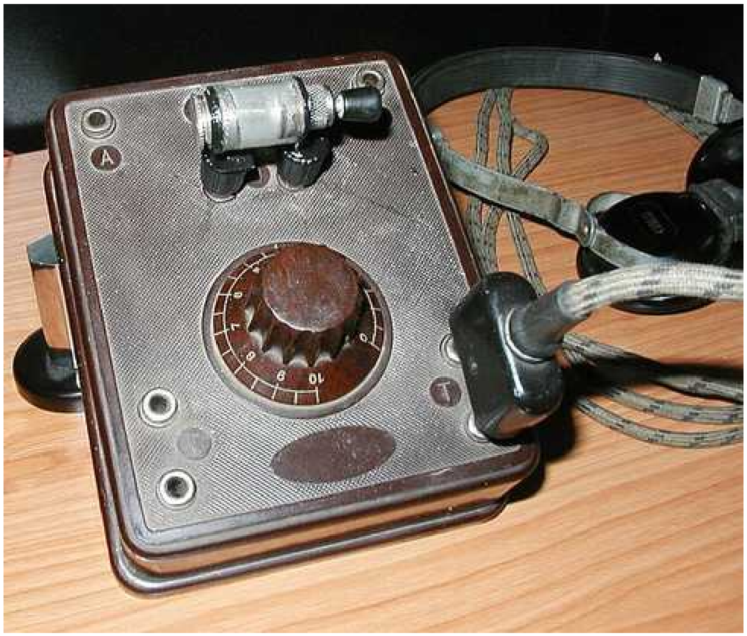
Above: The circuit diagram for the standard Crystal Radio



Above: A commercially made crystal set from around 1940

There is no variable tuning capacitor (condenser) in the above design. The capacitor is a fixed component and tuning is achieved by varying the coil inductance with the rotating switch. The detector is a galena crystal, seen at the top of the panel. A pair of high impedance magnetic headphones can just be seen to the right of this shot. (photo sent in by our reader Krysatec in Czechoslovakia - thanks!)

EXCELLENT RESULTS

Almost certainly when building a crystal set today a crystal earphone will need to be used. A crystal earphone is not quite as good as the old high impedance headphones as it is not quite as sensitive and therefore not quite so loud, however today's transmitters are much more powerful than those of the 1920's and so really excellent results are very often obtained - just don't expect to hear everything that you might on a top quality portable radio!

Crystal sets are fascinating because they are so simple to build, and because there is no power required they remain magical to this day. I have built several over the years, with differing designs, and if you'd like to build one yourself, it's easy, and I have described some circuits in part 2 with some more experimental ideas in part 5.

I have a crystal set that receives BBC Radio 4 on long wave and 3 local stations and 3 national stations on medium wave and another that also receives shortwave stations. Not bad for radios with no battery or other power - and such as set could be very useful in an emergency.

More About Diodes - unconventional and new ideas (by Felix Scerri)

While messing around with diodes for crystal sets recently, I tried something as a theory that actually works very well in practice, and with one or two actual advantages.

Ordinarily the ubiquitous 1N914 or IN4148 silicon switching diodes are pretty hopeless as RF detectors unless RF signals are *very* strong! However there is a simple way of making these diodes work very well as RF detectors, by the addition of adjustable voltage bias. I have used adjustable voltage bias with diodes before with very good results, but using bias with IN914 or 1N4148's is a relatively new idea!

Interestingly enough with voltage bias correctly adjusted, 'weak signal' performance and sound quality is actually very good, with that typically 'crisp' silicon diode 'sound'. I use a simple bias network with a 1.5 v AA battery and a 1 Megohm potentiometer applied to the diode directly with the incoming RF fed into the diode through a 1 uf plastic film capacitor (as shown). The use of adjustable bias seems to help most with 'repositioning' the position of the knee in the diodes curve and weak signal performance is excellent, easily as good as any 'proper' germanium diode.

Another 'tweak' that is actually quite beneficial is 'paralleling' several diodes together. This doesn't work with ordinary germanium diodes but definitely works with BAT46 'germanium equivalent' diodes and the effect of three of these diodes together is to make a better 'single' diode. The turn on voltage is noticeably reduced and the 'square law; region of detection is definitely improved and so is the rectified audio quality. These diodes are relatively inexpensive (at least in this country), so it is worth trying. 73 Felix vk4fuq 080214.

CRYSTAL SETS 3: CHRIS DORNA'S SPIDER'S WEB COIL

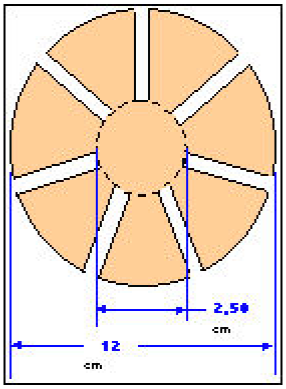
Making The Spider's Web

(NB. TRANSLATED FROM DUTCH
so I must apologise for any small errors)

See Chris Dorna's Website HERE!

Generally coils are cylindrical. We have chosen a spiders web coil because these are simple to wind. You must however pay attention that you lay the windings nice and tight when winding the coil.

The material chosen is 3.4 mm MDF as is easy to work with. If you make a former then you could also use an old CD perhaps.



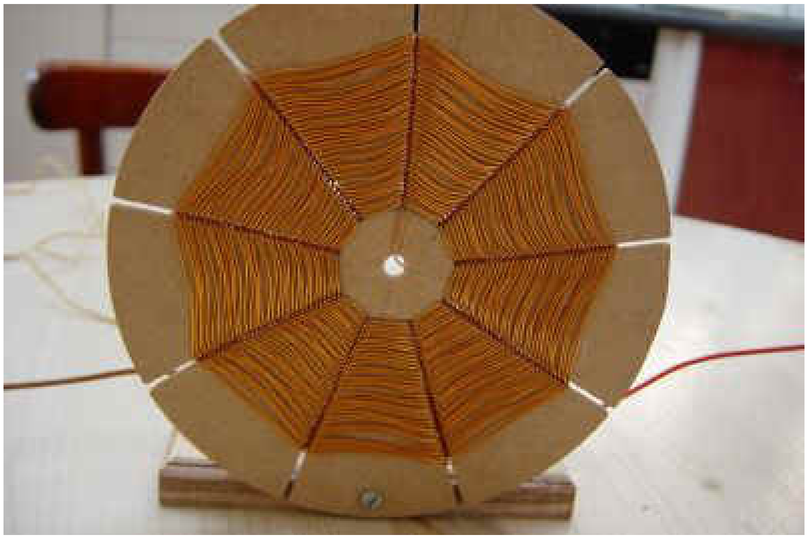
On the former shown on the left 7 segments have been created. For the crystal radio in the article below, the coil has been made with 9 segments at 40° intervals.

The inner diameter is 2.5 cm and the outer diameter is 12 cm.

The former is 4.75 mm thick and there are about 60-70 turns on the winding.

The wire should be reasonably thick as very thin wire can very easily break when winding.

For calculating the coil we used Professor Coyle's Spiderweb Coil Calculator



The Completed Coil

The Scouts "Jamboree On The Air"

Below are a couple of photographs of the completed crystal radio that the Vught North Scouts constructed during the their "Jamboree On The Air". The spiders web coil is a very interesting feature of the set and was chosen because it was thought to be easier to wind for the younger scouts.

The scouts were provided with a package that contained all the required components including the former for the coil, suitable wire to wind the coil and a base panel onto which they could build the spiders web crystal set on their Jamboree. They had to ensure, however, that great care was taken when putting up the wire for the large antenna for the wire which was a minimum of 10 meters long. The crystal set also had to be connected to an earth point and a water pipe was used for this.

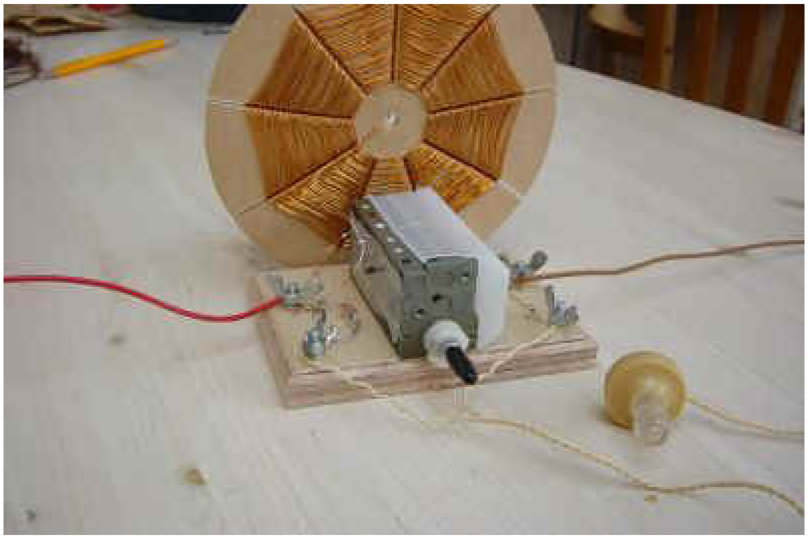


Photo showing the completed crystal set consisting of a germanium diode, a tuning capacitor and the spider web coil. The red wire is the aerial and the brown wire is connected to earth. The crystal earphone is shown in the foreground.

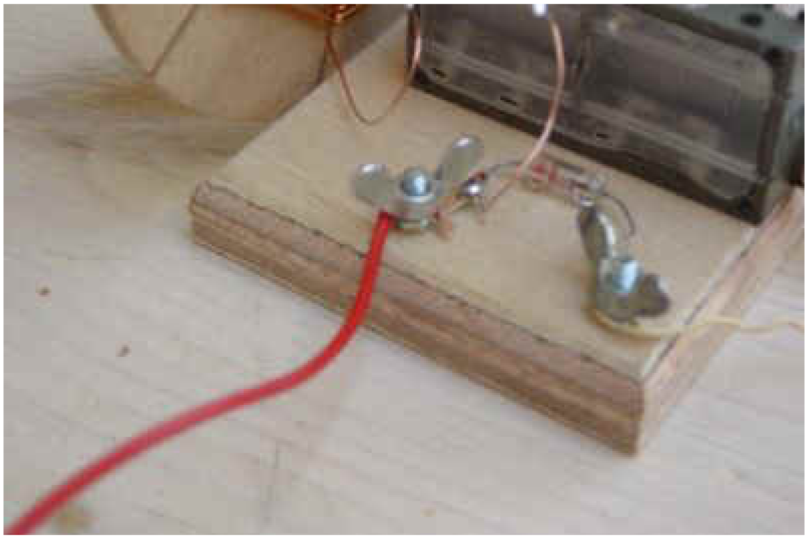

The germanium diode that converts the received radio frequency signal to audio that can be heard in the crystal earphone.

PARTS THAT WERE REQUIRED BY THE SCOUTS WERE PROVIDED IN THE THE PACKAGE:-

1	Base Panel
1	Coil Former
1	Tuning capacitor
1	Reel Of Coil Wire
1	Germanium Diode e.g. OA47, OA90, OA91, IN34 etc
1	Crystal Earphone
All	Screws and fixings required, tools, solder and soldering iron
1	Constructional Description with photograph Click HERE to download instructions. (7MB PDF File)

Despite the clear instructions provided there was soldering involved in the construction of the crystal set and the scouts were guided in this process by experienced members (such as radio amateurs) to ensure safety at all times.

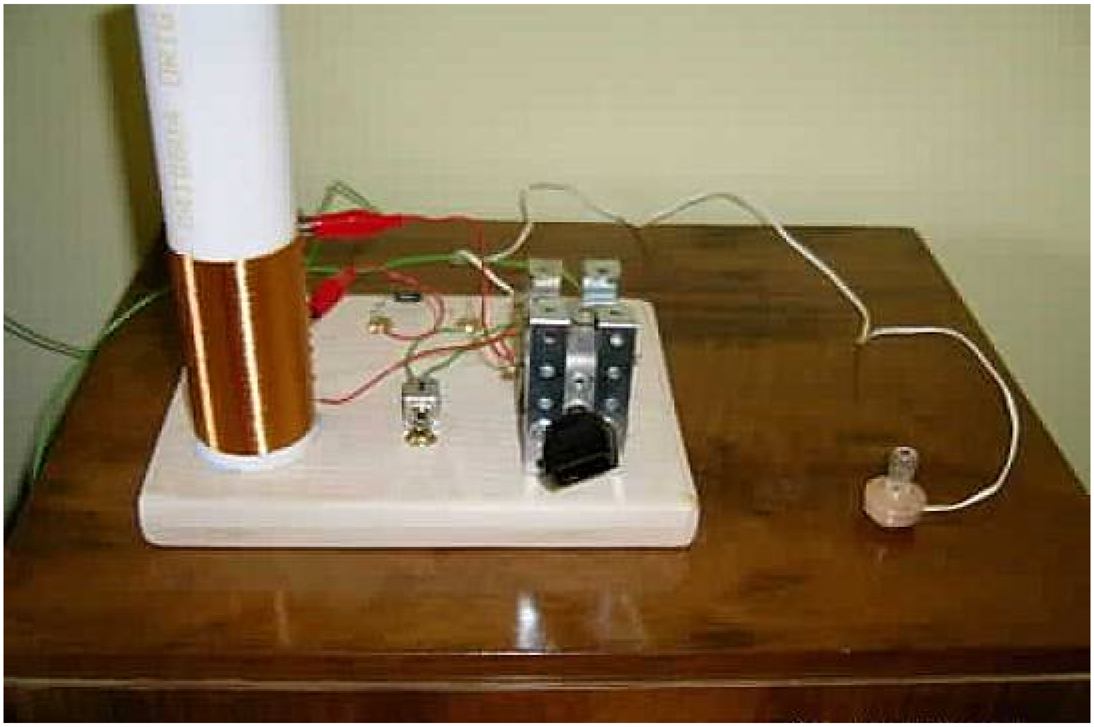
CRYSTAL SETS 4: A CRYSTAL SET BUILT BY KENNETH RANKIN

MDS975.co.uk reader Roddie Rankin kindly sent in the details of a crystal set built by his son Kenneth for a school project which won him great praise and merit. The crystal set is so nicely made and the project so well written that I thought it deserved a special page of its own.



Photograph Of Kenneth Rankin's Rather Super Crystal Set

CONTENTS

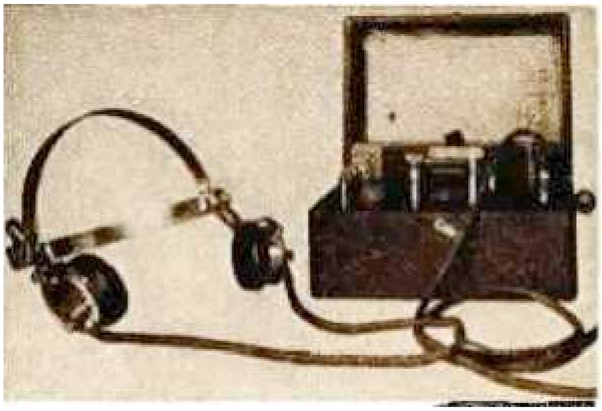
2 - How A Crystal Set Works
3 - History Of Crystal Sets
4 - How I Built My Crystal Set
5 - The Results I Obtained
6 - Where I Found The Information
7 - Quiz

1 - WHAT IS A CRYSTAL SET?

Perhaps you think, like I did, that a crystal set is just a collection of lovely stones. In fact a crystal set is a very early, simple domestic radio. The photograph above shows the crystal set I built.

The crystal set does not have a battery. It runs completely from the radio waves it picks up in the air. It is absolutely free to run!

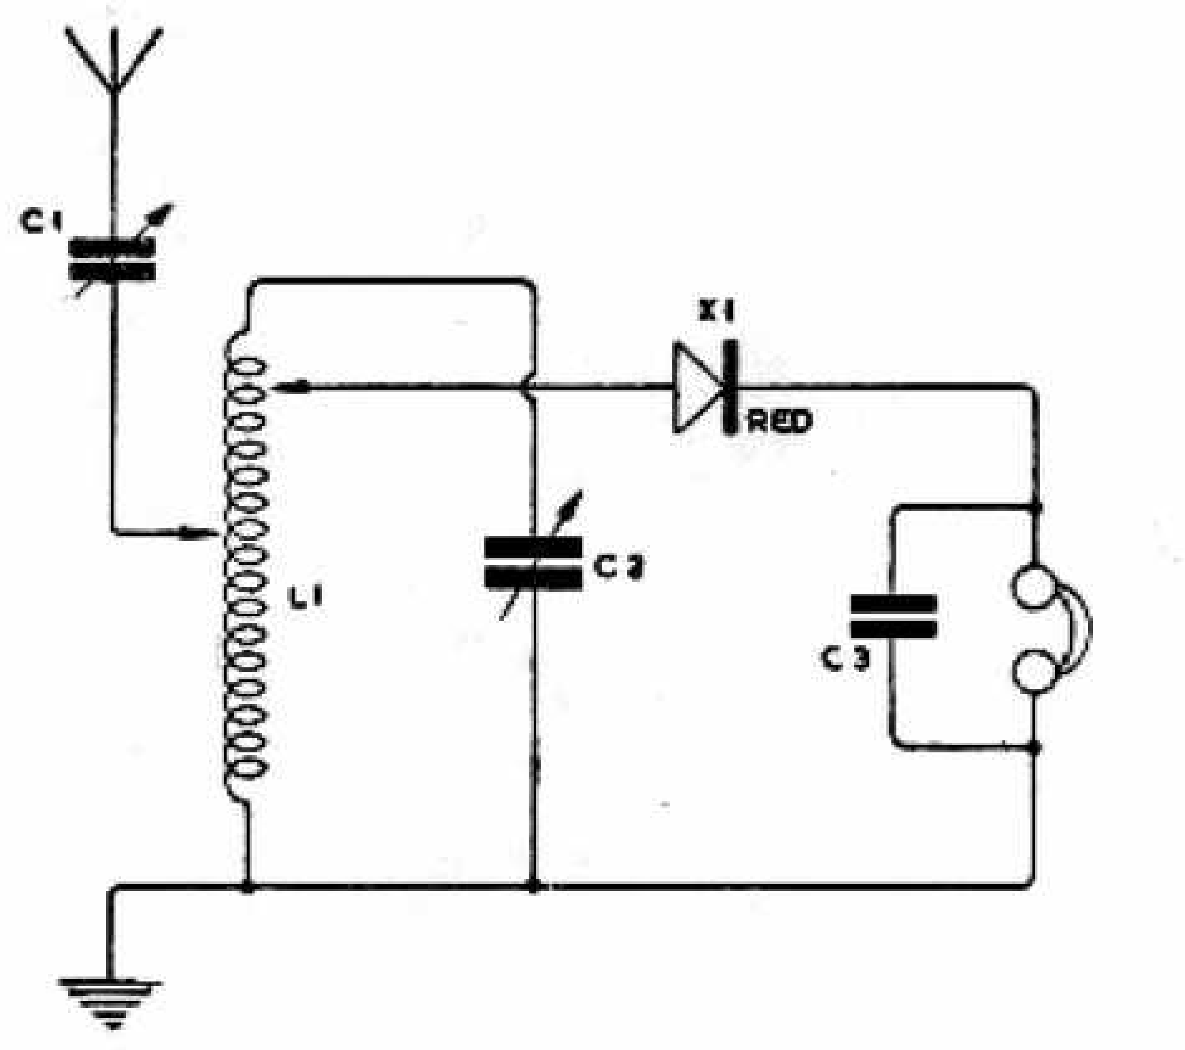
Please read on to find out more about this exciting invention!



The birth of domestic radio: A deluxe crystal set produced by Marconi for the reception of programmes from the first of the BBC's radio stations, 2LO in London.
[from Pageant Of The Century - Odhams Press]

2 - HOW A CRYSTAL SET WORKS

The diagram below shows the circuit diagram of the crystal set I have built. It consists of a coil (L1), a tuning capacitor (C2), a diode (X1), an aerial, a crystal earpiece and an earth. (Capacitors C1 and C3 are not essential.)



Circuit Diagram Of The Crystal Set

First the aerial picks up radio waves from radio stations all over the world. Then the required station needs to be selected, this is called tuning, and this is achieved with a Tuned Circuit. The Tuned Circuit in the crystal set consists of two items; a component called a variable capacitor and a coil of wire.

By adjusting the value of the capacitor and coil tuning is achieved. The coil taking unwanted signals of low frequency straight through to the earth, which gets rid of them, while the capacitor takes unwanted signals of high frequency straight through to the earth. The remaining signal, in between the high frequency and low frequency signals, is the signal of the required station which is not passed to earth by either the coil or the capacitor. This is the frequency to which the set is now tuned in.

You normally change the frequency to which a set is tuned in to by turning the knob on the tuning capacitor, thus receiving different stations by varying the capacitance of the variable capacitor. The number of turns on the coil can also be changed [called varying the inductance of the coil] and this will give different tuning ranges. A larger number of turns provided longer wavelengths [lower frequencies], while a smaller number of turns of wire provides shorter wavelengths [higher frequencies].

[It is also worth noting that the inductance of a coil can be increased by inserting a component called a Ferrite Rod into the centre of the coil.]

Once tuned into the required station this remaining signal goes to earth by travelling through the diode and earpiece. The diode takes the sound signal out of the radio signal [called demodulation], and passes it to the earpiece. The sound signal travels through the crystal in the earpiece which vibrates the air in the earpiece giving us the sound of the radio station to which you are tuned.

3 - THE HISTORY OF THE CRYSTAL SET

The history of crystal sets begins with the first broadcast stations being opened. This happened in England in 1922. The simplest form of receiver for these broadcasts was the crystal set.

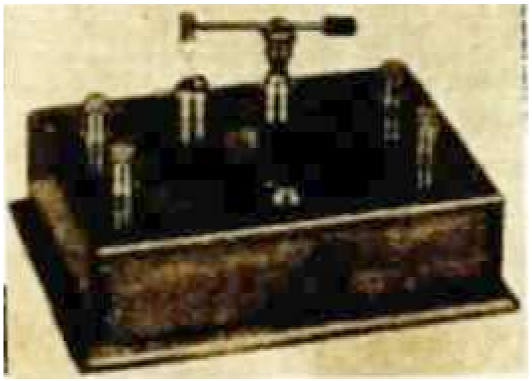
In those early sets they had "cat's whiskers" instead of diodes. A cat's whisker was a fine piece of wire which was adjusted to make a suitable contact with a crystal. The crystal would be made of a substance such as coke or galena. An example from 1923 is shown in the picture below. Notice how well made these instruments were.

There were several limitations to the crystal set: it needed a big aerial, an earth connection, the clumsy cat's whisker, and the weak signal could only be listened to by one person at a time with headphones. Very quickly the crystal set began to be replaced by valve radios with loudspeakers, powered by battery (see the picture from 1923).

In World War II, crystal sets were used by prisoners of war in prison camps to listen to news from home. As they were often badly treated it was hard to get all the right parts to build the set.

By this time crystal sets were no longer used in the home. Instead radios like the attractive 1937 model in the picture were being used.

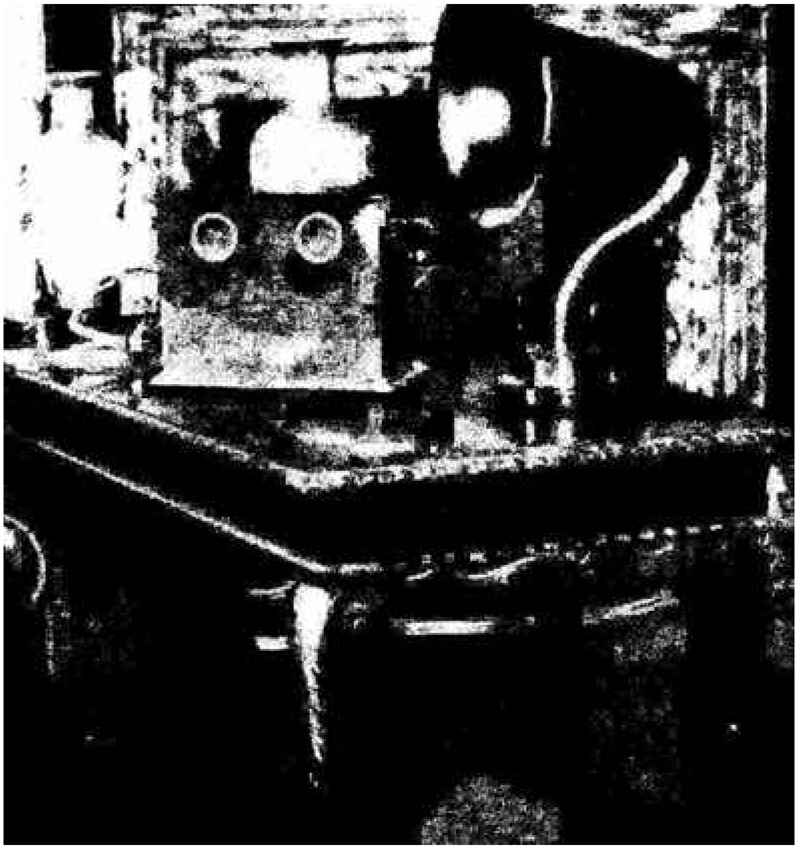
Nowadays people only use crystal sets as a hobby. There are various different kits available on the market (see websites in the references below).



Photograph Of A Crystal Set From 1923

[from Pageant Of The Century - Odhams Press]

Crystal sets were primitive instruments used for 'listening in', and were fitted with the now famous cats whisker. Listening was done though a pair of headphones which meant that only one person could listen at a time.



Photograph Of a 1923 Radio

[from Pageant Of The Century - Odhams Press]

Later valve amplification could be added to radios which allowed them to power a loudspeaker so that everyone in a room could listen in.

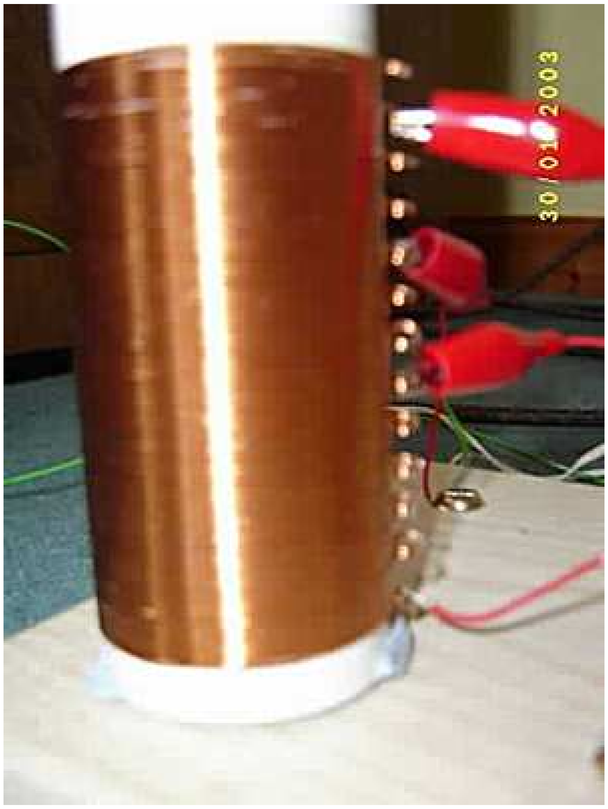
4 - HOW I BUILT MY CRYSTAL SET

The crystal set is a fun and easy thing to build.

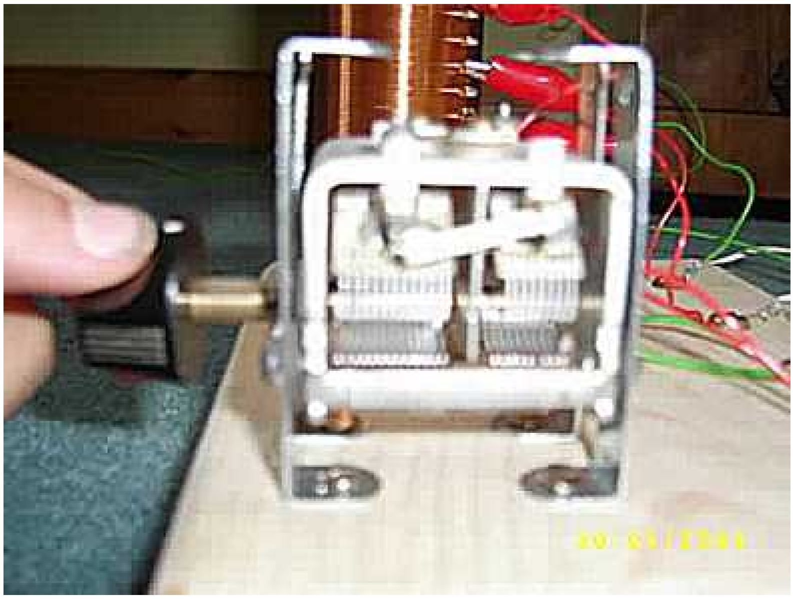
The first thing I had to do was put up an aerial and earth. For the aerial I drilled a hole in the ceiling and fed wire through the hole. Then I went into the attic and took the wire to the other end of the attic, fastening it to rafters as I went. When I got to the other side I fed the wire out of an air vent to the outside of the house. I then went outside tied wire to a nearby tree and joined it up to the wire coming out of the air vent. This gave me an aerial of about 25 metres.

Next the earth. For this I drilled another hole in the ceiling and fed another wire through and out of an air vent at the other side of the house (see previous paragraph). I attached this wire to the metal frame of my swing. This is a good earth because its poles stick deep into the ground.

The coil used enamelled copper wire wound on to a piece of plastic pipe with a diameter of 5 cm. There were 120 turns of wire. Every 10 turns I made a loop on which a crocodile clip could be fixed. See the picture below:

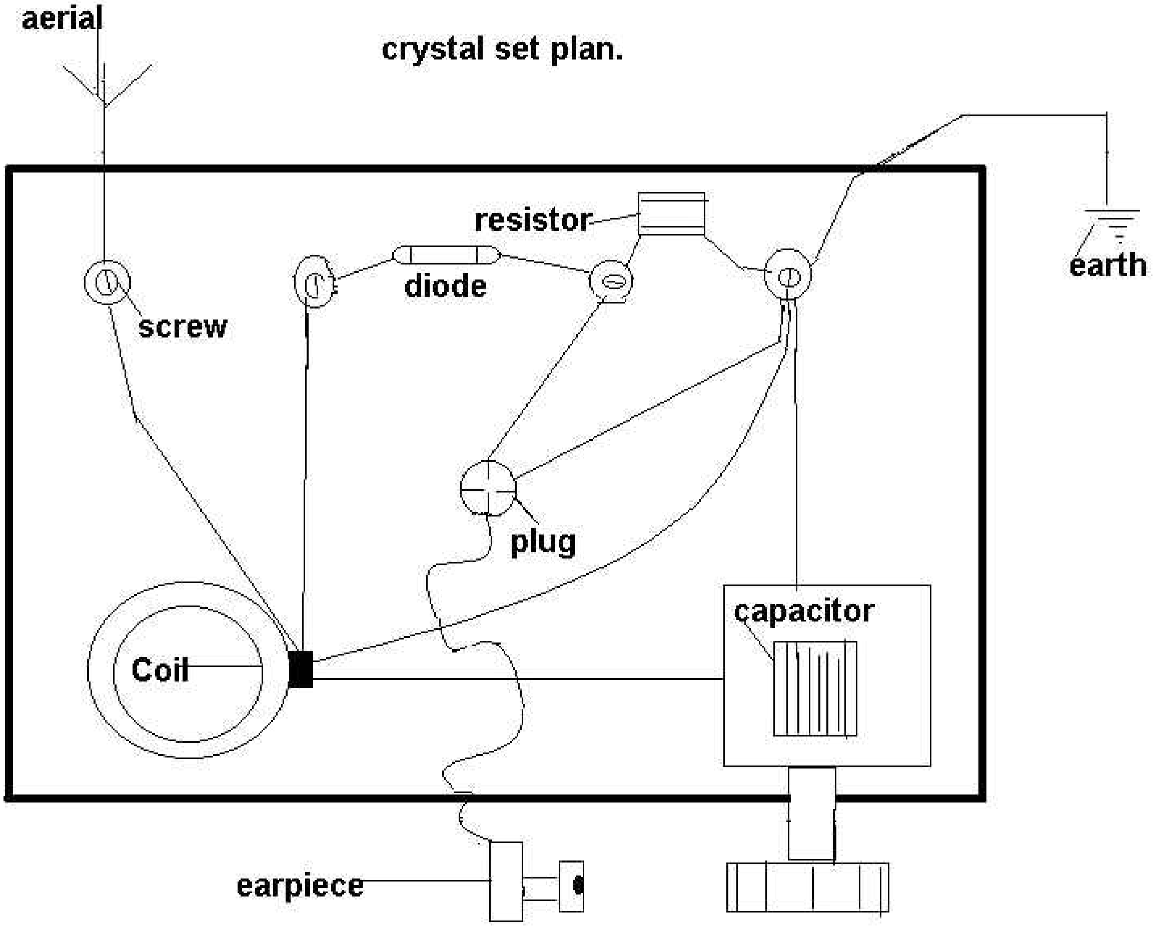


Photograph Of The Coil Showing The Tapping Points & Crocodile Clips



The Tuning Capacitor - Being Carefully Adjusted

For the crystal set itself, I first had to plan what I would be using and where the pieces would be placed (see picture and the plan drawing). I was using the circuit shown above. I built the crystal set on a wooden board about 20cm by 15cm. I drilled 4 holes 4cm apart. I put screws with cup washers in each hole and fastened the wires of the parts of the crystal set and the aerial and earth wires under the cup washers. I fastened the capacitor to the board using Meccano brackets and screws. The coil was fixed to the board using glue. The earpiece plugged into a socket which was fastened to the board using a thunderbolt shaped piece of Meccano.



Drawing Showing Layout Of Components

5 - THE RESULTS I OBTAINED

At first all I could hear was a foreign station. But then, I tried late at night and could sometimes hear a station from Florida in English! By tuning the capacitor and moving the crocodile clips up and down the coil I managed to receive a few foreign stations on Short Wave. What I really wanted was to tune in to Medium Wave. I wanted to receive English stations like Radio Scotland and music stations. I tried everything including a longer aerial and using different parts but to no avail. I came to the conclusion that I could not get a strong enough Medium Wave signal in Northerly area of Scotland where we live.

7 - QUIZ QUESTIONS

CRYSTAL SET QUIZ QUESTIONS:

1. What is a crystal set?
2. When were the first crystal sets sold?
3. Name 3 essential parts for a crystal set.
4. What does the earth do?
5. Does the coil pass signals of low frequency or high frequency?
6. How far apart were the screws on my crystal set?
7. What happened when I made the aerial longer?
8. What is this an anagram of: i a c c p r o t a?

(ANSWERS ARE FURTHER DOWN THIS PAGE)

PARTS THAT ARE REQUIRED

1	Wooden Base Panel
1	Coil Former 5cm dia. UPVC Pipe
1	Tuning Capacitor approx 500pF Air-Spaced or Solid Dielectric
1	Reel Of Enamelled Copper Wire for coil
1	Germanium Diode eg OA47 and IN34 which are especially suitable or other alternatives such as OA81, OA90 OA91, 1N94 etc
1	Crystal Earphone
1	47 k Ohm Resistor across earphone
6	½ inch No. 6 Brass Screws and Screw Cups
1	3.5mm mono Jack Socket
	Mounting Hardware (Meccano) for coil, capacitor and jack socket
	PVC covered wire for aerial and earth

A Superb RGD Valve Radio from 1937 - carefully restored in 1994 by Roddie Rankin

With thanks to Kenneth and Roddie Rankin for sending in this excellent article and photographs!

Crystal Sets Part 5 >

QUIZ ANSWERS

1. The first kind of radio
2. 1922.
3. Coil, diode, capacitor, earpiece, aerial, earth.
4. Gets rid of signals you don't want.
5. Low.
6. 4 cm.
7. It did not make much difference.
8. Capacitor.

No AM radio stations or transmitters in your locality or country?

Spitfire
AM Transmitter

Has your local medium wave broadcast station closed or been moved to VHF/FM or Digital? Don't worry. You can still build and experiment with crystal sets and TRF radios by also buying or even building a simple low power AM transmitter. So, not only can you use your crystal sets but you can also run your own radio station that can be heard in and around your home - playing the music or programmes that you want to hear!

SSTRAN AMT3000 : Superb high fidelity medium wave AM transmitter kits from SSTRAN. Versions available for 10kHz spacing in the Americas (AMT3000 or AMT3000-SM) and 9kHz spacing in Europe and other areas (AMT3000-9 and AMT3000-9SM). CRYSTAL SETS 4: A CRYSTAL SET BUILT BY KENNETH RANKIN

MDS975.co.uk reader Roddie Rankin kindly sent in the details of a crystal set built by his son Kenneth for a school project which won him great praise and merit. The crystal set is so nicely made and the project so well written that I thought it deserved a special page of its own.

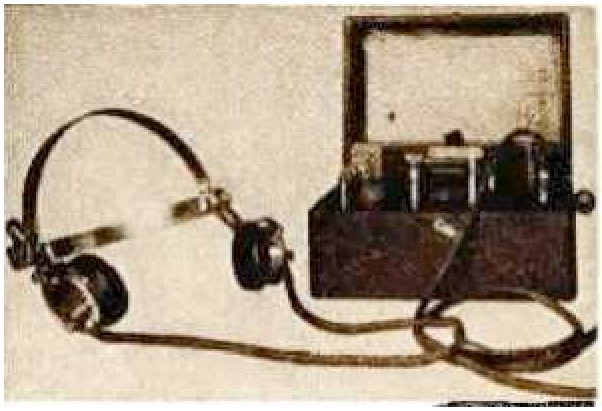
7 - Quiz

1 - WHAT IS A CRYSTAL SET?

Perhaps you think, like I did, that a crystal set is just a collection of lovely stones. In fact a crystal set is a very early, simple domestic radio. The photograph above shows the crystal set I built.

The crystal set does not have a battery. It runs completely from the radio waves it picks up in the air. It is absolutely free to run!

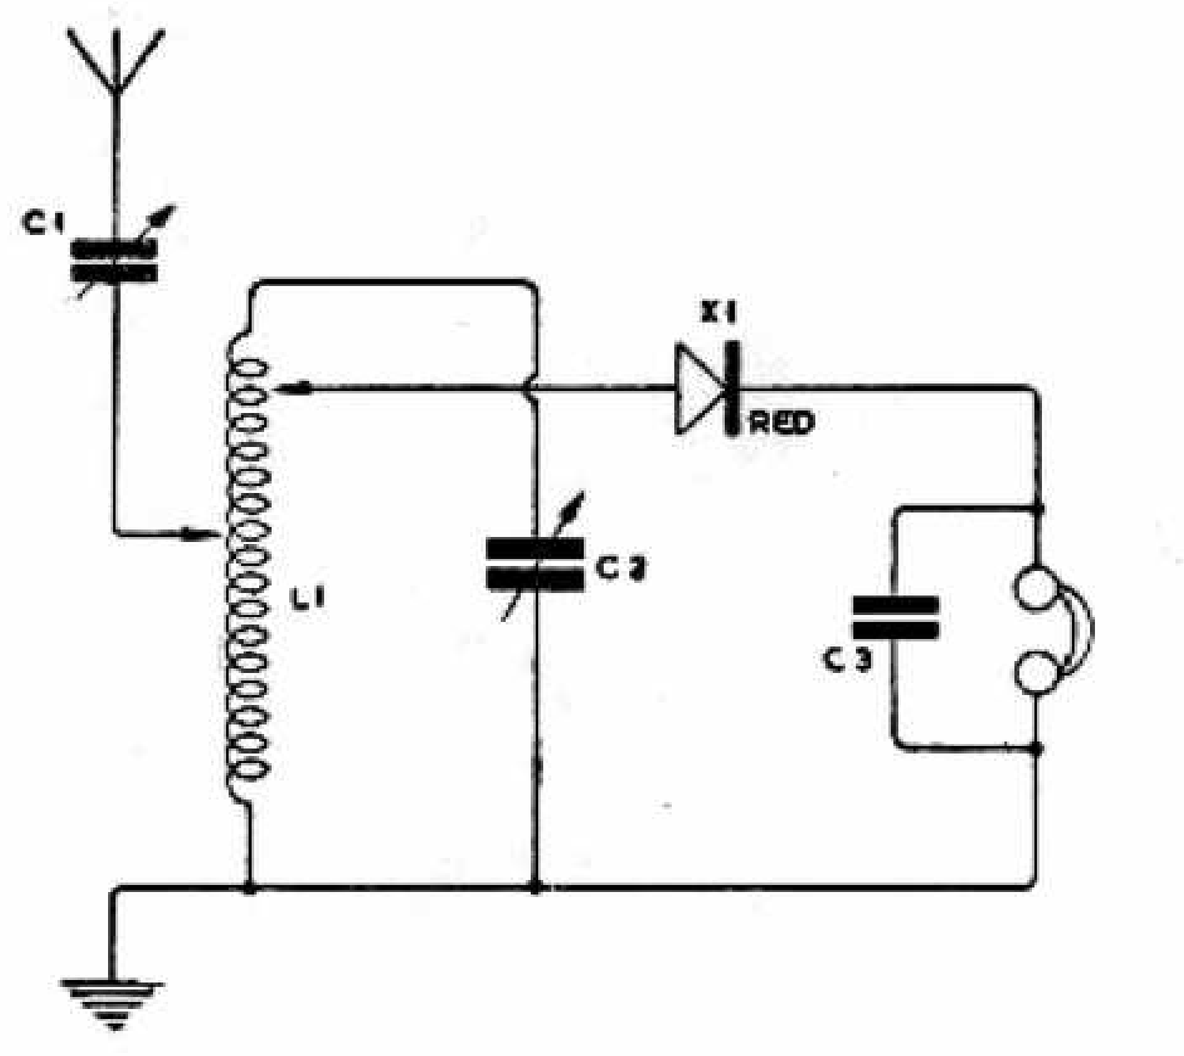
Please read on to find out more about this exciting invention!



The birth of domestic radio: A deluxe crystal set produced by Marconi for the reception of programmes from the first of the BBC's radio stations, 2LO in London.
[from Pageant Of The Century - Odhams Press]

2 - HOW A CRYSTAL SET WORKS

The diagram below shows the circuit diagram of the crystal set I have built. It consists of a coil (L1), a tuning capacitor (C2), a diode (X1), an aerial, a crystal earpiece and an earth. (Capacitors C1 and C3 are not essential.)



Circuit Diagram Of The Crystal Set

First the aerial picks up radio waves from radio stations all over the world. Then the required station needs to be selected, this is called tuning, and this is achieved with a Tuned Circuit. The Tuned Circuit in the crystal set consists of two items; a component called a variable capacitor and a coil of wire.

By adjusting the value of the capacitor and coil tuning is achieved. The coil taking unwanted signals of low frequency straight through to the earth, which gets rid of them, while the capacitor takes unwanted signals of high frequency straight through to the earth. The remaining signal, in between the high frequency and low frequency signals, is the signal of the required station which is not passed to earth by either the coil or the capacitor. This is the frequency to which the set is now tuned in.

You normally change the frequency to which a set is tuned in to by turning the knob on the tuning capacitor, thus receiving different stations by varying the capacitance of the variable capacitor. The number of turns on the coil can also be changed [called varying the inductance of the coil] and this will give different tuning ranges. A larger number of turns provided longer wavelengths [lower frequencies], while a smaller number of turns of wire provides shorter wavelengths [higher frequencies].

[It is also worth noting that the inductance of a coil can be increased by inserting a component called a Ferrite Rod into the centre of the coil.]

Once tuned into the required station this remaining signal goes to earth by travelling through the diode and earpiece. The diode takes the sound signal out of the radio signal [called demodulation], and passes it to the earpiece. The sound signal travels through the crystal in the earpiece which vibrates the air in the earpiece giving us the sound of the radio station to which you are tuned.

3 - THE HISTORY OF THE CRYSTAL SET

The history of crystal sets begins with the first broadcast stations being opened. This happened in England in 1922. The simplest form of receiver for these broadcasts was the crystal set.

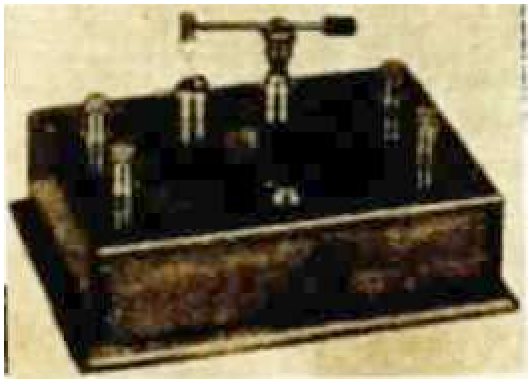
In those early sets they had "cat’s whiskers" instead of diodes. A cat’s whisker was a fine piece of wire which was adjusted to make a suitable contact with a crystal. The crystal would be made of a substance such as coke or galena. An example from 1923 is shown in the picture below. Notice how well made these instruments were.

There were several limitations to the crystal set: it needed a big aerial, an earth connection, the clumsy cat’s whisker, and the weak signal could only be listened to by one person at a time with headphones. Very quickly the crystal set began to be replaced by valve radios with loudspeakers, powered by battery (see the picture from 1923).

In World War II, crystal sets were used by prisoners of war in prison camps to listen to news from home. As they were often badly treated it was hard to get all the right parts to build the set.

By this time crystal sets were no longer used in the home. Instead radios like the attractive 1937 model in the picture were being used.

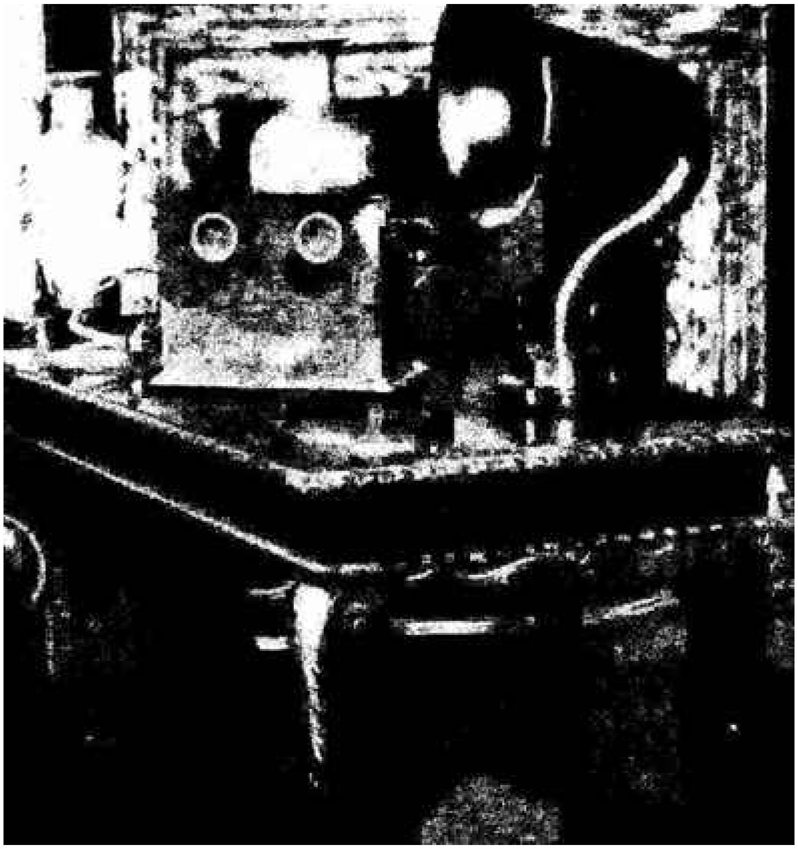
Nowadays people only use crystal sets as a hobby. There are various different kits available on the market (see websites in the references below).



Photograph Of A Crystal Set From 1923

[from Pageant Of The Century - Odhams Press]

Crystal sets were primitive instruments used for 'listening in', and were fitted with the now famous cats whisker. Listening was done though a pair of headphones which meant that only one person could listen at a time.



Photograph Of a 1923 Radio

[from Pageant Of The Century - Odhams Press]

Later valve amplification could be added to radios which allowed them to power a loudspeaker so that everyone in a room could listen in.

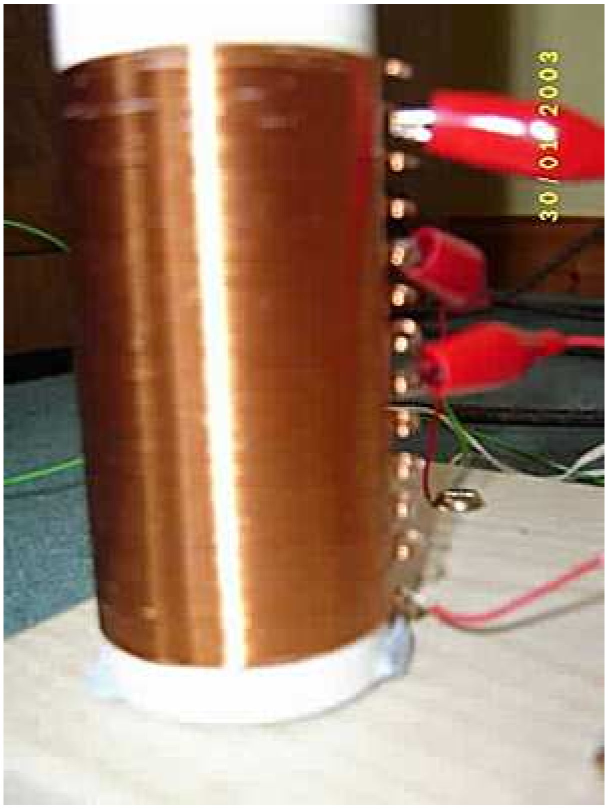
4 - HOW I BUILT MY CRYSTAL SET

The crystal set is a fun and easy thing to build.

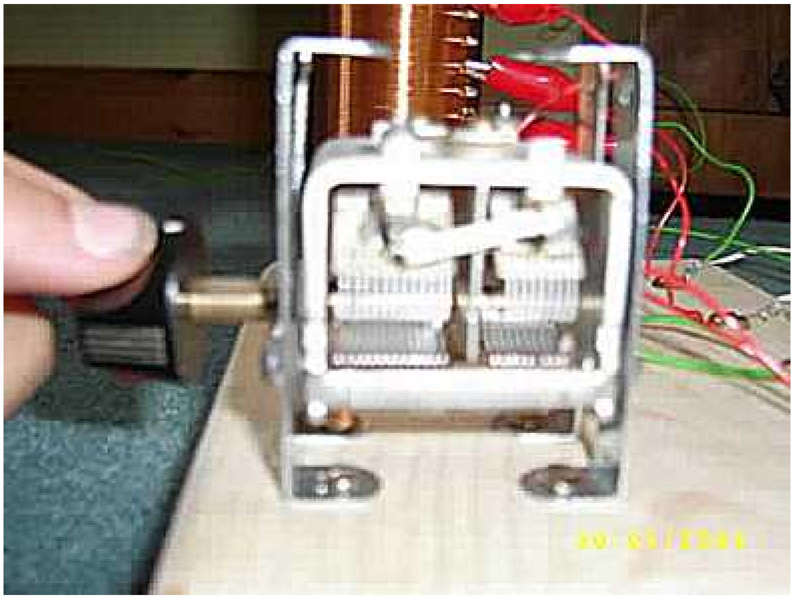
The first thing I had to do was put up an aerial and earth. For the aerial I drilled a hole in the ceiling and fed wire through the hole. Then I went into the attic and took the wire to the other end of the attic, fastening it to rafters as I went. When I got to the other side I fed the wire out of an air vent to the outside of the house. I then went outside tied wire to a nearby tree and joined it up to the wire coming out of the air vent. This gave me an aerial of about 25 metres.

Next the earth. For this I drilled another hole in the ceiling and fed another wire through and out of an air vent at the other side of the house (see previous paragraph). I attached this wire to the metal frame of my swing. This is a good earth because its poles stick deep into the ground.

The coil used enamelled copper wire wound on to a piece of plastic pipe with a diameter of 5 cm. There were 120 turns of wire. Every 10 turns I made a loop on which a crocodile clip could be fixed. See the picture below:

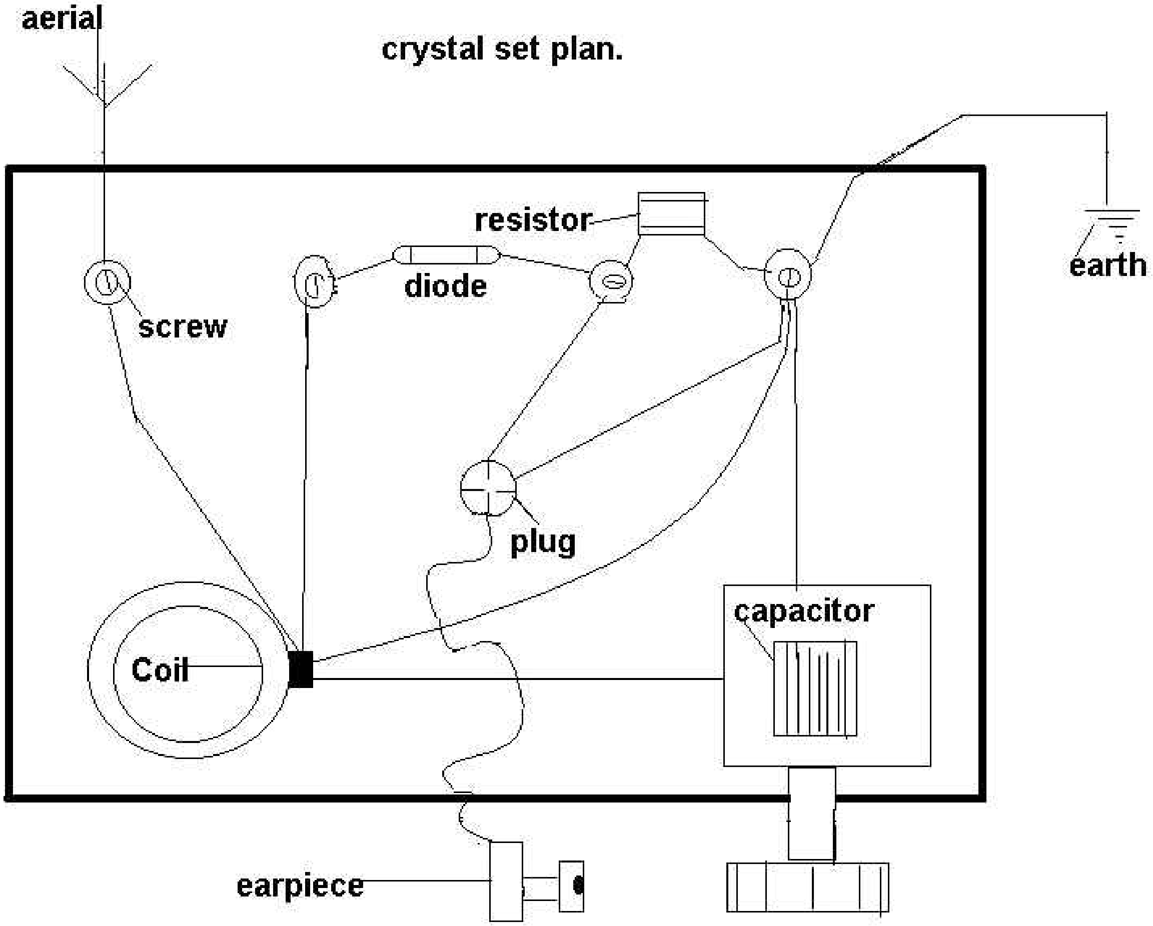


Photograph Of The Coil Showing The Tapping Points & Crocodile Clips



The Tuning Capacitor - Being Carefully Adjusted

For the crystal set itself, I first had to plan what I would be using and where the pieces would be placed (see picture and the plan drawing). I was using the circuit shown above. I built the crystal set on a wooden board about 20cm by 15cm. I drilled 4 holes 4cm apart. I put screws with cup washers in each hole and fastened the wires of the parts of the crystal set and the aerial and earth wires under the cup washers. I fastened the capacitor to the board using Meccano brackets and screws. The coil was fixed to the board using glue. The earpiece plugged into a socket which was fastened to the board using a thunderbolt shaped piece of Meccano.



Drawing Showing Layout Of Components

5 - THE RESULTS I OBTAINED

At first all I could hear was a foreign station. But then, I tried late at night and could sometimes hear a station from Florida in English! By tuning the capacitor and moving the crocodile clips up and down the coil I managed to receive a few foreign stations on Short Wave. What I really wanted was to tune in to Medium Wave. I wanted to receive English stations like Radio Scotland and music stations. I tried everything including a longer aerial and using different parts but to no avail. I came to the conclusion that I could not get a strong enough Medium Wave signal in Northerly area of Scotland where we live.

GALENE 1

commercial gales

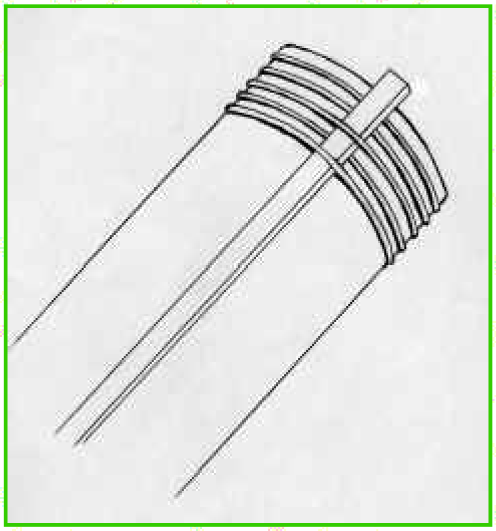
The classic commercial galen is of the Vaam type with double basket bottom coil of about fifty turns in parallel to the mica variable from 0-350 pf and is connected in Oudin. With the coil of this capacity we do not get to the short waves because for the resonance we have to calculate also the antenna capacity in parallel.
If we do not want to use a different coil for the high frequencies, it is better to add a socket that puts in series to the antenna a 100pf mica capacitor.

autocostruzione

If we dedicate ourselves to self-construction, the most convenient configuration uses a variable-spooling coil of 80-100 turns on a pipe of eighty millimeters. The wire must be 0.6 mm and the spirals must be spaced about 2 tenths of mm, otherwise we use Litz wire with an external diameter of 0.8-1 mm or the old bell-wire insulated in double cotton , and do not use any variable capacitors.

In the old achievements for the choice of the amount of turns it was done with a sliding slide on the stripped loops. This is not good because you always find at least a couple of coiled turns, which cause losses in the coil.

Another choice was to make, for example, 7 groups of 10 turns, selectable by a switch and a group of 10 turns selectable one by one. This however from too much capacity dispersed through the connections.



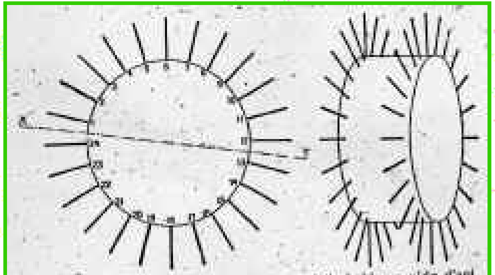


Fig. 124. — Mandrino per l'avvolgimento delle bobine a nido d'api

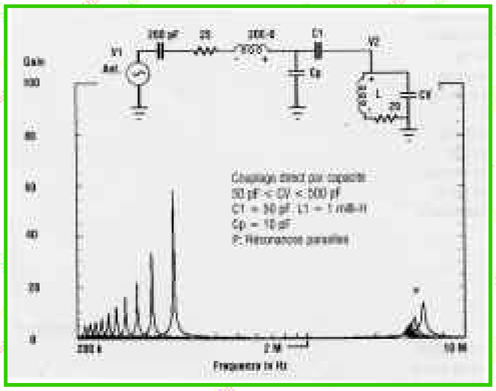
I chose to make the coil described by wrapping the coils as in the figure and inserting a thin wooden slat under the coils from which I want to make the grip. The pitch of the sockets is variable, dense initially and sparse at the end taking into account interpolation through the use of a small variable of 50 or 100 pf, a value that does little damage, considering the rule that the best yield of the galena is when the tuning is done with the coil only and without capacitors, either in series or in parallel. We will see later the realization of the Tesla circuit but already with Oudin the maximum results are obtained.

some notes

The crystal detection has the property to have a better performance to the strong signals than the weak ones: a weaker signal of 1.4 times in radiofrequency will be 2 times weaker in audio.

This phenomenon leads to a sharpening of the selectivity of the circuit, given that a small dissension is enough to multiply the signal reduction. Except for the case of Milan in the 1920s, where there were two strong stations nearby, the need for a great selectivity is not there. If ever, before the RAI reduced the power of its stations and decimals, a rejector could be needed to eliminate them. I talk about it in my publication IL LIBRO DELLE GALENE by Sandit.

intruders



The complaint of finding foreign stations in the evening, which can not be eliminated by tuning, is not due to its fault, but to the intrusion of short-wave stations on our antenna that solicit resonance modes in the antenna-galena system (Virtually every antenna has a resonance on the short waves and the addition of the chord coil fails to eliminate them.

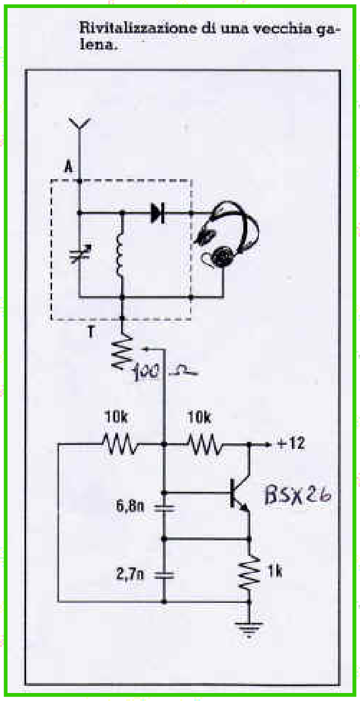
Frame

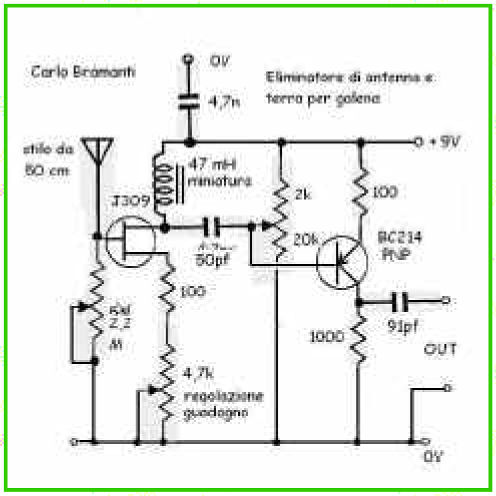
If we do not have an ideal antenna, but we must adapt to antennas on the balcony of a condominium in reinforced concrete, it may be appropriate to make a frame antenna. Any wired antenna has a much longer effective length than a frame antenna, but it also has a high loss resistance. A frame can have a very low resistance, with a Q even of 1000 and all accounts can transfer more power than a spun like in my case when I receive a double current with the frame. The diode, sensitive to the square of the tensions, works better, at the same power, if the tension is high, compared to a low, so the strong exrtatension of the frame with strong Q is advantageous.
I used a section of a 40 cm diameter wastebasket and skeleton constitution, using the detector I designed. However, a small 1 mH choke is required to eliminate the influence of the FM.
The one illustrated is optimized for the 1368 kHz made with three or better four lengths of conductor, in parallel, placed side by side. The L / C ratio is very delicate and if we want to go down in frequency we have to increase the coils, maybe reducing the wires in parallel, and increasing the capacity to maintain the same ratio that in my realization. For 1MHz we can orient ourselves on 13 turns, below 15-16. The performances are exceptional, except that in an interior of a modern building the reception is reduced to 1/3.

revitalization of an old galena

A simple ice galena in Oudin can become a formidable and sensitive tool without altering it, but simply by connecting the circuit board between the earth terminal of the container and the earth.
This is nothing more than a negative resistance amplifier that has the property of having common input and output and amplify in both directions. Appropriately regulated, it can oscillate in a heterodyne-beat reception circuit or it can stay at the limit of the oscillation, amplifying enormously like a jet device. The two capacitors of the divider may have unsuitable values for certain antennas and may need to be adjusted for stable reception.



Rivitalizzazione di una vecchia galena.



without antenna

If we want to give a demonstration of our galena where there are neither antennas nor earth, something that often happens at the markets, we can use a stylus of about sixty cm, adapting the very high reactive impedance with a high input impedance FET. The earth would become in our body or we can use a short length of hanging wire.

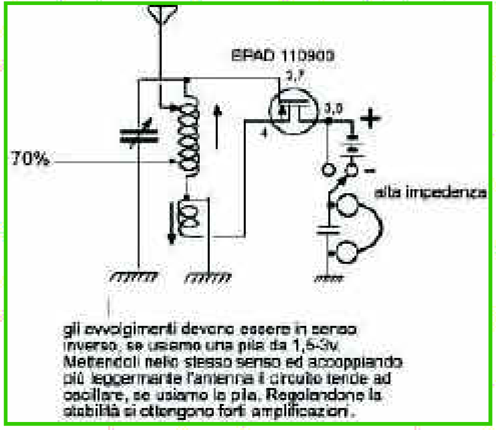
Requires construction experience but it works very well receiving distant stations, since the coil sends back the signal on the antenna with a reaction effect, to be adjusted with one of the potentiometers

help from new technologies

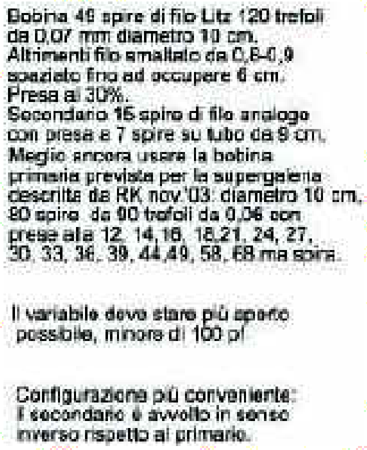
In a 2007 QST article, Bob Cutler introduces a new principle of revelation that is synchronous. In this he is helped by one of those technological miracles which is a MOSFET called EPAD which is satisfied with micropotencies and a supply voltage of 100mV; but something also happens with 10 mV, which is a virtually inaudible signal in galena.
The rectification function is made because the unwanted half-waves polarize the SURCE and inhibit the pitch to the wave itself, while the other half wave passes with good efficiency.

The rectification that we know in the diodes is due to the asymmetry of the curvature of the characteristic and the result is a quadratic trend of the response, ie the strong signal prevails over the weak. In our case, instead, the rectification function will be practically linear with enormous advantage for weak signals.

the original scheme foresees a ferrite rod with 70 turns on which they are wound 8 in the opposite direction, which are those going to the SURCE. I made it with coils in the air and as a result I can listen to the current Florence I, which was transferred far and near the shore at -48 dB, which is impossible with the OA95. With the AAZ17 series you can barely hear .



gli avvolgimenti devono essere in senso inverso, se usiamo una pila da 1,5-3v. Mettendoli nello stesso senso ed accoppiando più leggermente l'antenna il circuito tende ad oscillare, se usiamo la pila. Regolandone la stabilità si ottengono forti amplificazioni.



Bobina 49 spire di filo Litz 120 trefoli da 0,07 mm diametro 10 cm.
Altrimenti filo smaltato da 0,8-0,9 spaziato fino ad occupare 6 cm.
Presa al 30%.
Secondario 15 spire di filo analogo con presa a 7 spire su tubo da 9 cm.
Meglio ancora usare la bobina primaria prevista per la supergalena descritta da RK nov.'03: diametro 10 cm. 90 spire da 90 trefoli da 0,06 con prese alla 12, 14,16, 18,21, 24, 27, 30, 33, 36, 39, 44,49, 58, 68 ma spira.

Il variabile deve stare più aperto possibile, minore di 100 pf

Configurazione più conveniente: il secondario è avvolto in senso inverso rispetto al primario.

a p ila

My contribution was the simple addition of a battery in series to the headset: with a 3V alkaline button and an absorption of the microampere, I hear the station in the loudspeaker.
This realization is not a heresy because some diodes, too, see the old carborundum, provided for a feeding, and then, since these components are also available in SMD, you can make a small prism, big as a large diode, with three wires to be connected, without additional components, the ignition occurs when the headset is connected and we have a duration of at least 5 years without intervening.

stolen energy

The EPAD also adapts perfectly to stolen energy solutions, exploiting the rectification of a powerful station or the power supply buzz (see my book).

warning

This circuit can also be implemented with a simple Oudin by connecting to an intermediate socket. In this

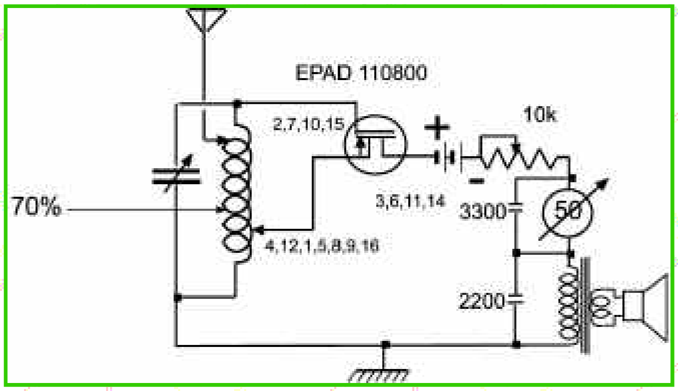
in case the turns have the same direction and without power supply there are no problems, but with the battery it becomes unstable, except to insert a resistance in series with the headphone. In this way the gain can be greatly increased, but becomes sensitive to the antenna characteristics. These components should be known to handle, inserted when everything is already on the circuit and do not do so many acrobatics. The EPAD is not easy to find, I took it from MOUSER USA to $ 1.91 each.

a big plus

This circuit, at least in my realization, does not suffer from intrusion by the short waves: in a direct comparison using an AAZ 17, in the dark, Florence I from Coltano becomes unlistenable because of these, while with the synchronous revelation I listen very well.
The battery can be 1.5 V or 3 volts, lithium button. The insertion of the battery allows listening in high impedance speaker.

Experimental realization : the coil has 5 cm of diameter, 80 turns of silver wire of 1mm arranged separated on two combs so to occupy 25 cm of length. Inside there are three 20 cm ferrite rods. It should also be provided that the selected crocodile does not come into contact with other coils . Capacitors are essential.

The performances are formidable!



EPAD 110800

This has the same functions as the previous one except that in the casing there are four mosfets that must be connected in parallel: gate = 2,7,10,15 surce = 4,12 drain = 3,6,11,14. Terminals 1,5,8,9,16 can be grounded or surce. The pin 5 is the return of the protection diodes. The absorption passes to about fifteen microampers, absorbed only when the headset is connected, more than double the previous circuit, but the power increases a lot allowing a very intense listening in high impedance speaker or with adapter transformer.

A frame antenna

For the 657 kc I made a frame antenna on the project described: 23 turns wrapped on the basket 40 cm in diameter using three 120 x0.07 litz wires, connected carefully placed side by side wrapping the backhoe uniformly to occupy about twenty cm. The grip of the surce is 1-2 turns if the battery is used, otherwise with 6 turns. The performances are equivalent to my row. Coltano also feels without feeding.

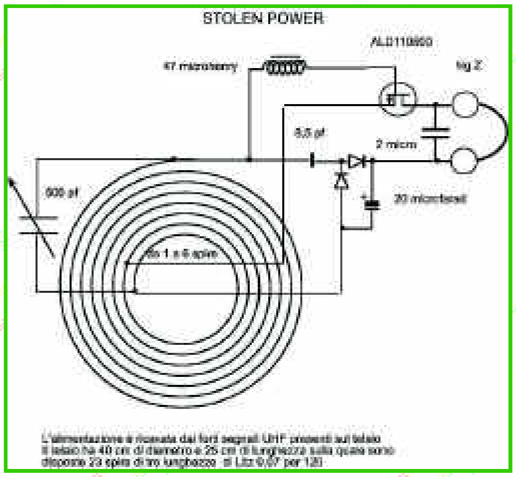
Notare il filtro contro l'interferenza
delle onde corte

The low power requirement of the EPAD calls for a stolen power supply. Of course we can not steal from the station we listen to, otherwise we would have invented the perpetual motion, but you can take advantage of the short wave stations holes, in the evening, or the network buzz, always. For the network hum it is sufficient to insert a 5000 pf capacitor between the base of the coil and the ground and rectify. Unfortunately, my 200 pf antenna at 50 hz present 20 megoohm of reactance and does not make it to power the complex, but other cases could be more favorable.

In the figure, a system that gave me positive results.

With the circuit shown my modest antenna results just enough, but in other cases it could give excellent: if you connect the test point to a chassis of some instrument connected to the network the voltage rises rapidly and gives excellent results. Excellent would also be with the light cap. Unfortunately, even if the synchronous detection is much more resistant to the interference of short waves than the traditional diode, in summer the weak Coltano veins me obliterated by those disturbances. So you can see in the diagram the introduction of the basic pass filter that goes well and does not attenuate. Careful to reproduce it faithfully as it is easy to get confused with links.



STOLEN POWER
ALD110800

6,5 pf
2 micro
500 pf
20 microfarad
da 1 a 6 spire
L'alimentazione è ricavata dai forti segnali UHF presenti sul telaio
Il telaio ha 40 cm di diametro e 25 cm di lunghezza sulla quale sono
disposte 23 spire di tre lunghezze di Litz 0,07 per 120

Note

I have been suggested to make an ideal rectifier for the detector made with one of the modern integrated circuits and the diode in reaction, as we find in the technical literature. I do not know if it's in our case better than normal diodes.

I tried an expensive zero bias diode from 35 euros but it does half of the AZ17.

Funziona ottimamente anche senza amplificatore, ma il livello e basso, per questo possiamo includere un'amplificatore o collegarla ad un impianto audio. Naturalmente la cavità risonante è piu selettiva, ma l'intensità è la stessa.

Electronic detector

There are various solutions for achieving revelation in a galena. Several are electronic. If we want to replace the detector with an already created galena, see the VAAM or the RUMA we have the problem that the electronic detector, even with a built-in battery, has three connection wires: antenna, earth and headphones. If we have only two clamps like the traditional detector, a solution must be found to transform the quadripolo into a dipole. The problem that arises is the return to ground of the headset, meaning that of the amplifier that is the negative pole of the power supply.

This is done so that the return occurs through the antenna coils and a radio-frequency stop coil. In this way the device can be inserted in place of the traditional detector.

In the first figure a counterweight connected between the diode and the rheostat can be useful

NOTE

There may be problems with the condenser on the headphone which it is better not to put on. Also the headset used must be low impedance, about 600 ohms. With a 4000 ohm headset, it may not work

in the second figure we see the transistor construction and below that with the integrated 7642

The weakening of the medium wave stations no longer allows us to experiment with the entrance circuit, the corner stone of the galena. We had already lost the thrill of exploring with the cat whisker, using the more stable germanium diode AA143 or AAZ 119, but that had made the nickname "galena" improper. At this point the electronic revelation that brings us back to the experimentation of the input circuits and of the coupling principles that are the basis of the radiotechnics.

The evening disturbances of nearby stations and even those of short waves are so toned. In the evening at the spectrum analyzer I see the local station at -40 dB, a densume of stations between 1400 and 1600 kHz, at the local level or higher, the waves of the 6 MHz range, with many stations always at the level of my local, then something about 12 MHz. After increasingly weak signals. Unfortunately, if a simplified calculation our input resonates on a medium wave station, a deeper calculation appear answers on the short waves that, if they happen on 6 MHz, interfere with our listening, thwarting our efforts to obtain selectivity ..

Already in the '15s in the military receivers did not look so much at the selectivity of the entrance, since the stations were not so many and you could eliminate the disturbers by centering them with the rejector. This can still be done in particular in commercial gales that suffer a lot from interference. : take a ferrite of a radiolina, let's put the classic variable at the ends of the windings and bring it closer to the coil, generally honeycomb, centering with the condenser the area where the disturbances appear. Note that the rejector can also be used for tuning by keeping the main capacitor fixed. It is an interesting experimentation

Something better

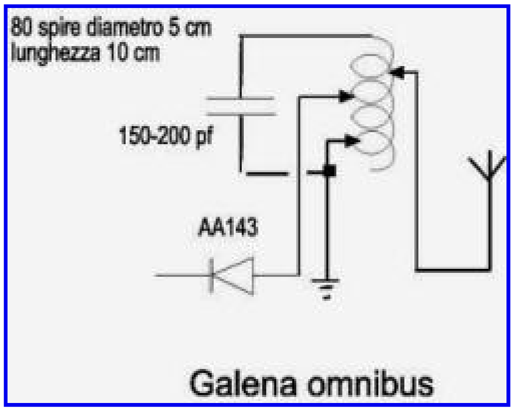
What I recommend is a cylindrical bobbin of 10 cm in diameter with 49 turns of Litz thread of 120 strands of 0.07, or of the insulated wire of 0.85-0.90 mm separating if turns with a fishing line. Then two sockets at 1/3 and 2/3 of the winding. Col Litz overcomes the Q of 400 compared to 180 of the normal coils. With that the performance increases a lot 'and the interference decreases. Better if you make the "supergalena" from my publication "Il Libro delle Galene". The condenser on the cuff may be advantageous or not depending on the case.

electronic detector

With the integrated 7642 or MK 484 of the described electronic detectors, reception is very good, but AVC, even if it eliminates interference, makes experimentation more difficult. Then I found several faulty integrals. With the NPN-PNP arrangement, experimentation is possible again and the sensitivity performances are similar to those of the integrated and the loudest volume.

GALENA OMNIBUS



THEat recent reductions in RAI stations in the ether, it did not discourage galene enthusiasts, rather it invited them to improve their antennas and perfect their circuits. During the day, only the local station is received, often with difficulty, so selectivity is not important and a good performance circuit like Oudin is enough. In the evening, however, the entry of many foreign stations confuses reception and requires greater selectivity. The maximum would be obtained with a Tesla arrangement, but it is complex. A circuit that is ideal for selectivity and sensitivity is the Oudin in a three-cursor omnibus configuration. One serves to partialize the coil with reference to ground and fixed condenser, another serves to optimize the socket for the diode, finally the ideal selectivity is obtained with the antenna cursor.

The coil is cylindrical, 5 cm in diameter and 10 in length. The coils are 80 of the largest possible wire, enamelled or, better, with double-cotton insulation that must be peeled corresponding to the sliders.

The principle

The coil of the galena itself can have a Q from 200 to 400, taken alone. If we apply the antenna and the earth to its ends, we transfer the entire antenna loss resistance, that is, about sixty ohms in series to the resistance of the coil loss that is of very few ohms. Thus the Q passes to a fortnight, with consequences on selectivity. If instead we connect the antenna to an intermediate socket, we compensate for the reduction of the signal due to the divider, but we increase the Q by restoring the original overvoltage until reaching an optimal value for both. By reducing the coils on the antenna again at some point we will have the maximum selectivity but less signal.

Another cause of damping of the Q is the load due to the detector. Also for that the grip on the reel should be optimized. This for two cursors. The third is to expand the range of frequencies received and to optimize everything.

Galena FM and flat

My approach to FM was to derive from the strong signal present a little bit of continuous voltage to amplify a galena amplifier to stolen power. The antenna that gave me the best results at the time was the J antenna that I described from various parts.

FM revelation

Since revealing the stations on the side of the selectivity curve it was also possible to listen to FM stations, I used it just for that. Unfortunately, as commonly stated, the intensity of the audio obtained is very poor and it is better to amplify than low. Using resonant cavities I was able to listen comfortably even without amplification, but the problem was to move the antenna away to place it in a place with more signal. Unfortunately I did not manage to couple it with a cable, except for high losses, higher than the natural ones of the cable.

A flat

I then resumed the TV plate dipole that had given me bad results in the beginning: the problem was that, by agreeing to the iconography and what is studied at school, I kept it horizontal. Since, instead, the FM broadcasts are usually vertical polarization, I hung vertically, with the horizontal output plate, and I obtained excellent results such as to allow me to listen, slowly but comfortably without amplification. In the case of the cavity, which has a 50 ohm unbalanced input, the situation improved with a Balun 4: 1.

Stolen feed

Given the excellent results that gives me a circuit to a transistor that I normally use in the AM galena with stolen power, and the high continuous voltage that you can now get (almost 1 volt, on my balcony), I tried to apply it to the galena FM . It already works by connecting on the same signal plate, but the results vary during the day. Since it is not a drama to hang a second band, I used this solution for feeding, with excellent results.

Results

Generally this solution gives me 0.85 Volt and 100 microampers on 400 ohms (the internal resistance of the power supply is about 8000 ohms). It is ineffective the solution of the condenser of 0.1 Farad that I was recharged with detached headphone in the case of 50 Hz in AM (the internal resistance was 15 Megaohm, so the drop given by the absorption was high, now not).

Easier

Simple coil

Applied the ribbon antenna in the old single coil FM galena, the strongest stations felt comfortably without amplification. Better still to stolen power, except in this case the energy can not be made from the signal antenna, but a specific one is needed.

With a dedicated plate for power it is even better, but it works even without the amplifier.

An amplified frame antenna

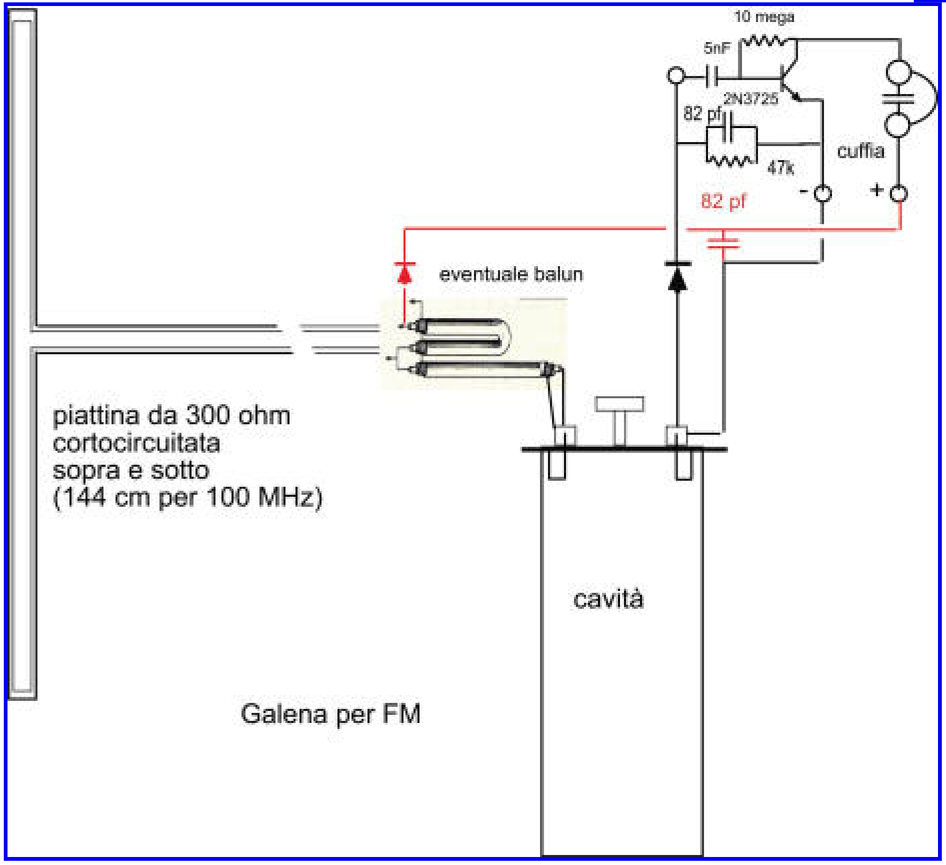
If we can build a frame antenna of a very high Q, we can compete with a mediocre line, but the signal is always little and there is nothing to be scandalized if we try to amplify.

In order not to remain on the cattle with a common amplifier, we experiment a solution with a negative resistance amplifier, which also has a considerable didactic implication. These are very particular amplifiers that present the input at the same point of the output and are able to amplify in both directions. For this they were used in telephone lines ...

The criterion is to present itself as a negative resistance, that is to avoid the resistances of the circuit eliminating the losses and even bringing the stage towards the oscillation. In the purely radio field we see it applied to the Q multipliers on the average frequency of the 50s receivers.

We have already used it in the galena with wired antenna, with great success., See the figure below.

Applied to a framed antenna, the matter becomes more critical and delicate, but with a lot of effort we can do it. The rheostat must be adjusted so that the oscillation is not excessive and the station whistle can be intercepted. At that point you adjust the variable and rheostat until the voice appears. If 220 ohm is not enough for the rheostat, try 470.



The great thing about this solution is that it does not need to build a frame with a special conductor, so the amplifier thinks about the losses.

In any case, if we want to lessen less, we have excellent results by applying to the chassis the 2 transistor amplifier several times described by me.

You will notice the insertion of 47 microhenry choke coils that serve to eliminate the FM signal that is present in the vertical section of the frame, dangerously saturating.

Introduction

The ultimate goal for all traders is consistent and reliable profits, with a trading operation that allows confidence, security and predictability. Now you may be thinking “Yes it is, but there is so much uncertainty in the markets. How am I ever going to be able to do that?”

While it is true that no one can predict the markets, you can make the uncertainty of the markets a non-issue, thus removing it from your trading. No one has control over the markets, yet there are numerous traders that enjoy trading as described above and they also enjoy consistent and reliable profits year after year as well, trading the same un-controllable and unpredictable markets that you do.

By the end of this report, you too will know exactly how to take the uncertainty out of your trading, and how to raise your confidence and security tremendously on your way to predictable, reliable and profitable trading.

Now, it is important for you to understand something here. This report is being kept extremely brief for two reasons: 1. I respect your time, so I am not filling up pages simply to give it enough “weight” to justify the meager price; 2. I am a firm believer that many solutions don’t need to be 500, 300 or even 100 pages to communicate the core ideas and information. Often this can be accomplished in only a handful of pages, so I try to keep my works as brief and concise as possible. This particular topic does not warrant an entire book, although there are certain matters brought up which do, and at those points I’ll recommend specific resources so that you can explore them further if you so choose.

This report is not intended by any means to tell you everything you need to know about trading. It is intended to raise your awareness to a specific and commonly overlooked problem, give you a simple and effective solution, and then also to give you a different perspective on your trading and how you approach the challenges before you as a trader.

The first part of this report details the problem and the solution. The second part then expands on the approach so that you can make use of it in other areas of your trading. It is my intention with this report to give you a new look at your trading business, and one that serves you well.

Part 1 – A Very Specific Problem

Let me begin by raising your attention to this: if you find this in your trading and choose to not to address it, you are leaving yourself open to a whole slew of emotional challenges in your trading, along with making some of the known best-practices in trading very difficult, if not impossible.

Since releasing the Trading Performance Analyzer, I've had conversation with many traders about backtesting and the importance of system analysis and tracking your key metrics. The reason that many of those conversations was taking place was because the person on the other end of the phone was at the point of struggle and frustration with their trading and they were very excited at prospect of being able to use the Analyzer to help them understand why their past success was eluding them now.

As we got to talking in more detail, they'd tell me about what they'd done in the past and where they were now with their trading. I'd ask about the system they were using and if they'd been able to identify what had changed or what they were trying to get back on track. Usually at this point they'd tell me that they had used this strategy or that and traded in these markets before but now had also moved into other markets, perhaps also making some changes to their system by incorporating different indicators or twists on the methodology.

Now these things are fine and quite commonly done, actually expected. As you develop and grow as a trader, you naturally want to put the things you discover or learn of into use, so your trading system will evolve. That is only natural.

When we got to the point where I asked if they had their trading system written down, the answer was usually half "Yes" and half "Well, sort of" or "Not really" or just plain "No".

The one thing that was common amongst all of them was their answer to the next question: “Is your system well-defined, and are the decision points clear to you?” After some thought, the answer was “No, not really.”

After some further questions, we’d come to the conclusion together that they were trying to trade with a rather discretionary system and / or a mixture of systems, but not a consistent system that was clear and well defined. What they employed on a given day might be subject to a variety of things, and certainly not the same from one week to the next.

Again, back to the goal of consistent profits.

Whether your system is very clear and written down or if it is totally random, you still have a system. The more random it is, the less likely you are to have consistent results, regardless of what the market does. On the same note, the clearer and more consistent your system is, the more consistent your results are likely to be, again, regardless of what the market does.

Now this presents a different challenge: how do you know if you have a clear and well defined system? How clear is clear enough? How well-defined is enough? I bring this up, because even those that had their systems written down, still did not feel that it was as clear as they’d like when we pursued it thoroughly. How do you know?

The Specific Solution to the Problem

At this point, let me share a bit of my background in my previous life outside of trading, because the solution I am going to give you is applicable in many areas, both specific to the business of trading and businesses in other industries.

You see, uncertainty is something that all businesses have to deal with, and there is a specific methodology to addressing it. I personally developed an addition to that methodology that works outside of trading, but is especially effective for the problem at hand, in trading.

I used to be a Quality Manager, which meant that one my primary functions was to ensure that our manufacturing operations ran consistently, efficiently and as cost-effectively as possible.

One tool integral to that effort was the Quality Manual. Now many people have no idea what a Quality Manual is. Simply put, it is the document system which defines the operation and everything that goes on in the operation. Its purpose is to make clear to everyone in detail how the company intends to achieve its goals.

A Quality Manual consists of layers of documents, each answering different questions:

1. Top level: Mission and Vision statements which detail the future of the company and what is to be accomplished
2. Next level: Policies which give an overview of the company rules that are set in stone, and these support the mission and vision statements.
3. Procedures are next and define the general activities of the business, and for each of those activities, answer the questions of:
    a. What is to be done (described generally)?
    b. Why are we doing it (its purpose)?
    c. Who (is responsible for making this happen)?
    d. When (or how often) is this activity to be performed?
    e. In what areas is this applicable (physical or departmental)?
4. Work Instructions support the procedures and answer these questions:
    a. What is to be done (specifically)?
    b. What are the steps to do this task?

Creating these documents can be quite a challenge, where you are defining what people are to be doing on a daily basis. Ideally these documents are clear and complete to the point that those following the procedures and work instructions can do their jobs consistently and according to the established best practices.

When we were first developing the document system, there were many procedures and work instructions written that were NOT clear and wound up needing many revisions. People would have questions in order to do the task at hand, and taking the time to get answers interfered with their efficiency. Either that or things would be done in a random fashion, depending on who was on shift that day or how they were feeling.

In the Quality Department, we had to make sure that all the activities and tasks that mattered (which was most), were documented and documented well. The level of documentation and the clarity and completeness of that documentation were in direct proportion to the consistency of the results, be they product quality, production, general housekeeping, accounting, customer service, etc.

As I trained others to write procedures and work instructions, I found a very effective method for creating these documents in a manner such that they were clear, complete and did not need revision for years.

Here’s the method for the creator of the work instruction:

1. Go through the entire process yourself, writing down every step you take
2. Find someone in the plant that knows their way around (assume that they do know the basics in that area), but hasn’t performed that specific task before and have them go through the work instruction.
3. Write down every question they have, and note anything they miss
4. When you can give the work instruction to someone new to the task and they can do it exactly as you expect and without question or assistance, then you are done. If not, repeat steps 2 and 3.

So how does this apply to the problem at hand, with one’s trading system?

> **When you have your trading system documented clearly and thoroughly to the point that you could hand it to another trader, and they could trade it the same as you without questions or assistance, then you have a sufficiently well-defined system.**

Making the Uncertainty of the Markets a Non-Issue

Now this also solved another problem encountered by the people I spoke of earlier. They were having a tough time trying to backtest their system, because of its lack of clarity. When an activity (like trading system execution) is unclear and variable, it is difficult to repeat. But that is exactly what you are doing when you backtest. You are taking your system back in time and running it through its paces repeatedly to validate it and understand the associated metrics.

Back to our goal of consistency: consistency comes from repeatability in what we do. When your system is clearly and completely defined, especially all the decision points, it becomes very repeatable and thus consistent and reliable.

Through backtesting and determining your system's metrics, you'll know how many winners and losers to expect, what average return-per-trade to expect, what your profit-to-loss ratio is. This is the point where the uncertainty of the markets becomes a none-issue with regards to your trading system.

If you have your trading system thoroughly defined and documented, and then backtest it properly and track your actual trading performance, you'll know what to expect from your system regardless of what the markets do, uncertain as they may be, because you'll have a repeatable and reliable system and you'll know the metrics associated with that system when traded with real market data.

For a very user-friendly and printer-friendly application for backtesting to get your system's metrics, plus a basic guide for backtesting, check out the Trading Performance Analyzer at http://www.insideouttrading.com/tpa/

Part 2 - Taking the Uncertainty Completely Out of Your Trading

Now back to the parallels between trading and all other businesses, and how you can capitalize on what we've discussed above to take the uncertainty completely out of your trading.

Like I mentioned before, all businesses have uncertainty to deal with. A business is not a building, equipment, computers, software, vehicles or machines. A business is people making things happen. It is an operation that involves people and those people are engaged in activities that make it a business.

As a Mechanical Engineer, I learned a long time ago that it doesn’t matter how great things work on paper. You can design the most magnificent machine or equipment layout ever, but when you take it into the real world, you have to include people into its function.

What was truly enjoyable about my time as a Quality Engineer and Manager, is that I got to deal with processes that included both the machines and the people running and maintaining them. The reason that Quality as a business approach and the Quality Manual have taken on increased significance over the years is business leaders have come to understand that profitability is very closely tied to the focus that the business has on quality, both in product and service delivered, but also within the operation itself.

In a process, variability represents risk. The reason that the Quality Manual is of such importance is that it reduces the variability in what the people in the company do. As more and more activities within the company are systemized and clearly defined and documented, the more consistent the company runs. This is the foundation of franchising – building duplicable businesses that can be run with generally available labor – and produce predictable profits, regardless of what town you put one in and who’s going to be working in your franchise business.

Back to trading.

Part of the problem here is the wording. Most traders think of a trading system the way it is defined by Investopedia.com:

> A trading system is simply a group of specific rules, or parameters, that determine entry and exit points for a given equity. These points, known as signals, are often marked on a chart in real time and prompt the immediate execution of a trade.”

By this definition and way of looking at one’s trading system, it is easy to understand why so many traders think that when they sign up for a signal service or buy a particular software package that gives them buy and sell signals, they think that they have a trading system. But they don’t. Not really.

You see, trading is a process, not just a set of rules and signals. That process is a series of actions, it is an activity, and is best defined by procedures.

I bring up the point that your trading is a whole process, not just a trading system to illustrate the importance of reducing variability, thus eliminating uncertainty. Your “trading system” must include everything that impacts your trading results. There can be many factors that introduce variability, and I’m talking about things in what you do, not the markets.

A lesson that we can learn from Quality is to focus on the process before focusing on hitting the target. In manufacturing, process control is imperative to producing in-spec product. If a machine process is both highly variable and off the target specification, there are two approaches that can be taken. You can try to center the process, then reduce the variability or you can tighten the process and then center it. In the automotive industry, the Japanese will generally focus on the process first, then the target, whereas American car-makers often focus on hitting the target first, then tightening the process. Needless to say, the process-focused approach usually reaches the end-goal with considerably much less time and money involved.

Same goes for trading. Understand that your trading system is more than a set of signals and rules. It is a process, an operation. Many people start trading and think that as soon as they have a “trading system”, they have a trading operation. They don’t. That is only one part of the business.

Your trading business is like any other business in certain respects: you have an owner (you), and a worker (you, the trader), probably an accountant to do your books (maybe you, maybe you hire one out), a computer technician for installing software (again probably you), head of Research & Development, etc. etc.

The point is, as the owner of your trading business, you have many hats to wear, many roles to fulfill. As with the trading system, you have a business whether you treat it as one or not. As you define your roles and document the activities for each of those roles more clearly, the more repeatable and predictable your business will become. In the Subtle Trap of Trading, I detail all of the aspects of your trading business, so you might find it helpful to take a peek at it. There are numerous aspects to your business and it is valuable for you to define those roles, document the associated activities and periodically switch hats and fulfill those roles – but with intention, not haphazardly.

Conclusion

One very common problem that traders struggle with is a lack of clarity in their trading system. Perhaps trying to get too technical, or just wanting to find that something that works causes one to introduce variables and inconsistencies into the system, thus adding to the uncertainty of it to be repeatable and reliable.

Without clarity in one's system, you leave yourself open to a host of problems. Most of all deviations and decisions that result in regrettable losses. You'll find it difficult to trade and backtesting will be dicey at best and of little value.

Make sure that you clearly and completely define your system to the point that you could hand it to another trader and have them trade it the same as you. Then you've got a clearly defined system that you can measure, track and improve.

You trading is a business, and the more clearly you define the roles and activities in your business, the more certainty and repeatability you bring to your operation as a whole.

The markets will have their uncertainty and there is nothing you can do to try to control the markets or predict them. You do however have total control over yourself and what YOU do. When you take control of yourself and your operation, you will effectively make the uncertainty of the markets a non-issue and you'll take the uncertainty completely out of your trading.

About the Author

Brian McAboy is a degreed Mechanical Engineer and Certified Quality Engineer, along with being a trading enthusiast.

I hope that you've found this report useful and enjoyable. As you can tell, I take a business approach to trading and bring learning from my roles in other areas of my life here for your benefit.

There are many things to learn and digest as you develop into the trader you wish to be, and there are stages to the development. To assist you and help you accelerate your progress, I've created several resources for you and you can find out more about them at http://www.insideouttrading.com

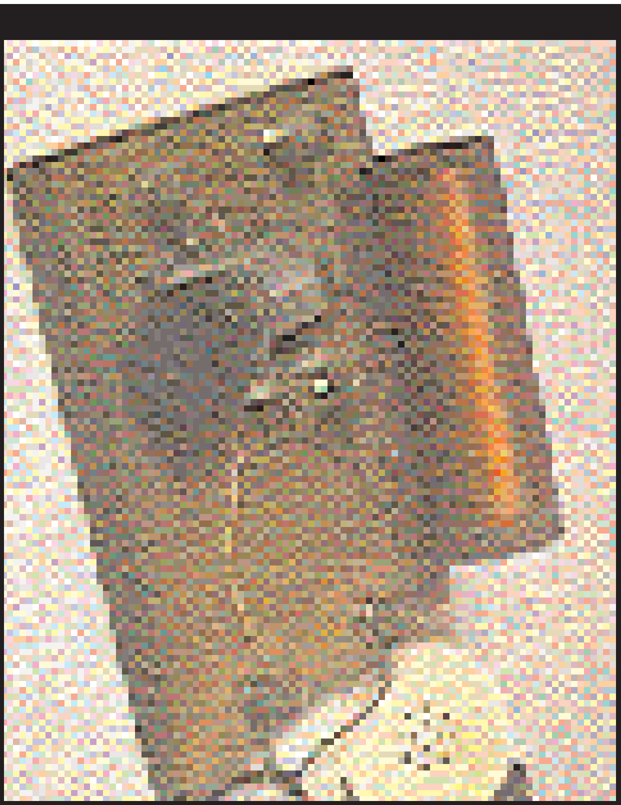
CRYSTAL RADIO KIT

gti kit™ 8893



GIBSON TECH ED, INC. 1216 S 1580 W OREM, UT 84058 1-800-422-1100

(A) List of Parts provided in the CRYSTAL RADIO SET

1. 8 Brass furniture thumbtacks
2. 70’ of Copper magnet wire #30
3. 1 Large paper clip
4. 1 - 470 pF disc capacitor
5. 1 - 0.01 µF disc capacitor
6. 1 - Germanium diode
7. 1 - Crystal earphone with wires
8. 2 - Alligator clips with wires
9. 1 - PLMCRS1 instructions

Parts you need to obtain:
1 cardboard tube (toilet papertube)
1 board (wood, 71/2” x 5”)
sticky tape (to hold coil you make)
quick drying varnish, nail polish, or clear radio cement

Tools Needed:
needlenose pliers
a small hammer
wire cutters

(B) Project Description

*The complete **CRYSTAL RADIO SET KIT #8893** includes everything you need except for the wood baseboard, the cardboard tube from a toilet paper roll and varnish, nail polish, or clear radio cement to paint the coil.*

*This little project is a sure interest grabber with students of electronics of any age! It does not require a great amount of skill, but a little application will produce a good basic radio receiver. Construction is fairly simple. **This radio DOES NOT require batteries** to operate, using simple electrical principles to power itself.*

This circuit is for the simplest radio receiver that can be practically constructed - yet it is the basic building block of more highly sophisticated and complex units.

(C) SAFETY FIRST

***DO NOT** attempt to use an electrical wall outlet, or connect to any electrical appliance to ground your radio. Use a cold water tap, or “ground stake”.*

***DO NOT** mount your antenna near to, or over the top of, electrical power lines of any type. If your antenna wire should break it could contact the live power and a severe **ELECTRICAL SHOCK** and possibly **DEATH** could occur.*

***DO NOT** leave your antenna coupled to the radio when it is not used, as it is an attraction to **LIGHTING STRIKES** and/or violent electrical **STATIC DISCHARGE**. Place the free end of the antenna **OUTSIDE** and clear of the building or connect it direct to earth.*

***DO NOT** operate the radio during the approach of, or during an electrical storm .*

GIBSON TECH ED, INC. 1216 S 1580 W OREM, UT 84058 1-800-422-1100

(D) Operating instructions

*In order for the radio set to work you will have to connect it to an **ANTENNA** and a **GROUND.** In some locations an antenna may not be necessary, but a good ground connection is very important. A cold water pipe is usually the best to use, or you can put down an "earth stake" and connect to it.*

The best antenna for this radio can simply be a really long wire, mounted as high as possible. Good results can also be produced by using metal bed spring frames or a fence. Be creative!

Crystal radios are not very selective, nor very sensitive. Several stations may be heard at once, many of them equally as strong as the others. A long antenna (30+ meters) will improve the strength of some stations, helping you tune them in a little more easily.

Operation is that simple.

(E) Theory of Operation

The crystal radio works by creating an oscillator with the coil and C1. The placement of the wiper along the coil varies the amount of inductance in parallel with the capacitor. This tunes our radio by determining the oscillating frequency. The signal is then rectified by the diode and smoothed out by C2. The resulting signal causes a thin ceramic crystal in the earphone to vibrate creating the sound that we hear.

(F) Reading Comprehension

1. The wiper varies the amount of_______________in parallel with the capacitor.

2. The signal is___________by the diode.

3. The crystal _________________ vibrates to create sound.

(G) Complete Parts List

- A (9cm x 13cm) or (7.5in. x 5in.) block of Pine wood, or chipboard.(not included in kit)
- 8 BRASS flathead thumb tacks.
- 2 Alligator Clips, one for antenna, one for ground.
- A discarded cardboard roll from a toilet paper roll.(not included in kit)
- L1 - 70' of 30 Gauge Magnet wire for approximately 145 turns around the cardboard roll.
- A large wire paper clip.
- 300mm length bare copper.
- C1 - A 470 Picofarad ceramic disc capacitor.
- C2 - A 0.01 Microfarad ceramic disc Capacitor.
- D1 - A Germanium Point Contact Diode Type OA90.
- E1 - A CRYSTAL earphone

(H) Schematic Diagram

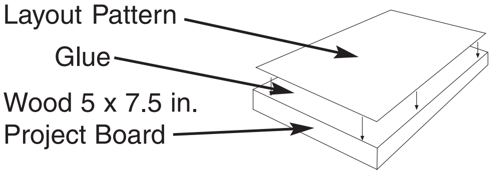
(I) Assembly Instructions

Tools needed:

A small hammer, a pair of wire cutters and a pair of needlenose pliers are all the tools required. A roll of household sticky tape is handy for holding wire in place as you wind the coil.

Step 1 (Wood Project Board)
Cut a piece of wood to 5" x 7 1/2" x 1/2"

Step 2 (Layout Pattern)
Cut out the Layout Pattern and glue it to the wood.



Step 3 (Coil)
Prepare the tube to wind the coil. Measure and cut a 7cm length of the tube. Draw a line all the way around the tube to use as a guide while cutting. Draw two more lines 1cm in from eather end. Cut tabs on both ends exactly across from each other then fold them in, out of the way for cutting off the extra tube length. (See Fig. 1)

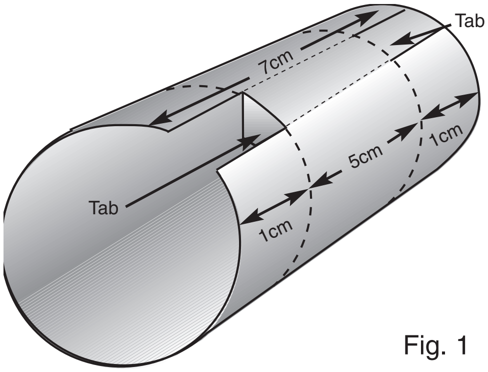


Fig. 1

Step 4 (Coil)
Using scissors, cut the extra length from the tube. Do not cut the tabs off as they will be used to hold the tube to your wood project board.
The easiest way to cut the tube straight is by placing the flat of the scissors against the folded tab and following your line around as shown in Fig. 2.

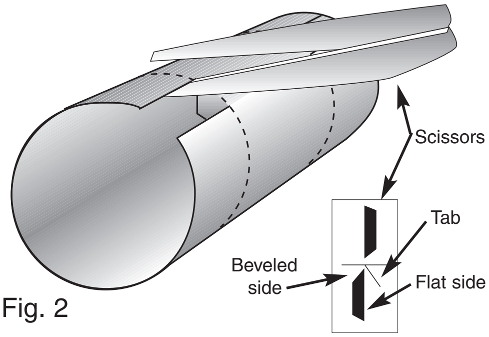

Fig. 2

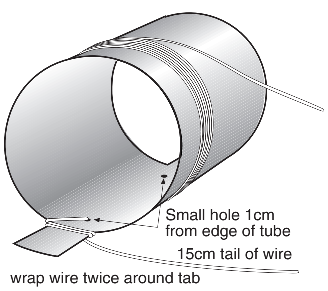

Fig. 3

Step 5 (Coil) (See Fig. 3)
*Make a small hole with a tack, 1cm in from both ends of the tube. Push 15cm of the wire through from the outside of the tube to the inside and wrap the wire tail twice around the tab at one end, this prevents the wire from slipping as you wind. Starting 1cm from the edge of the tube firmly wind on as many turns as will fit between the two holes (approximately 145 turns,) ensuring each turn is straight and tight together **no gaps!***

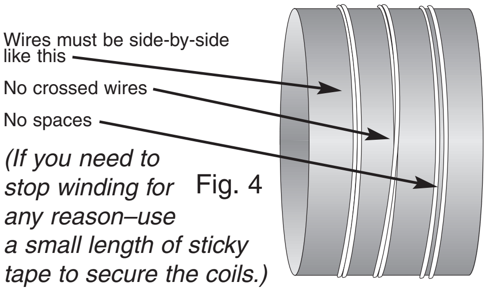

Fig. 4

(If you need to stop winding for any reason–use a small length of sticky tape to secure the coils.)
When you reach tab #2, trim off the wire to 15cm and wrap it twice around the tab. A coat of quick drying varnish or nail polish will secure the coil loops permanently. Coat the cardboard tube at the same time and place the assembly aside to dry.

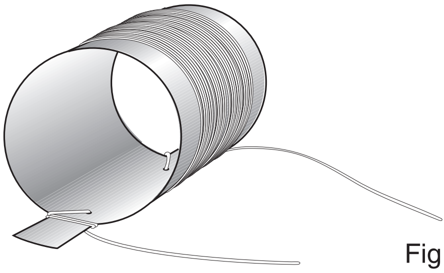

Fig. 6

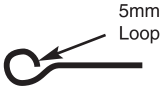
Step 6



Straighten out a paper clip with pliers and a hammer. In one end make an open loop 5mm in diameter. This paper clip will be used as a wiper on the coil. (See the Pictorial Diagram page 4). All the components and wires are secured with furniture tacks no soldering is required.

For a better connection to the tacks make small loops at the ends of the wire leads on the capacitors and diode and the copper wire which joins the various parts of the circuit together.

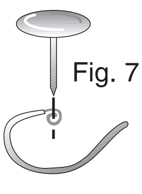


Fig. 7

Step 7 (CoiL)
*Attach the Coil you just made to the board as indicated by the pattern, placing the tacks through the tabs of the tube. (You may need a small hammer to tap the tacks down tightly.) **Do Not** hammer any other tacks down into the board until **all** the other parts have been properly positioned.*

Step 8 (Wiper)
Place the wiper in position on the board and rest it against the coil. From this you can see where the coil will need to be scraped free of insulation. (This area on the coil is shown as a white stripe on the Pictorial Diagram page 4.) The enamel insulation and varnish you coated the coil with can be removed using a fine cut file or fine grit emery paper–taking care not to displace or break any of the coil turns. Make bare an area about 10-15 mm wide, across the face of the coil. The coating also needs to be removed from the leads, then they can be wrapped around the appropriate tacks "A" and "F".

Step 9
*With the straightened paper clip acting as a **WIPER,** the coil will be a **VARIABLE INDUCTOR** (See the Pictorial Diagram page 4). The free end of the wiper is bent at an angle so that it will wipe along the bare wires of the inductor when secured in place on the baseboard.*

Step 10
Identify the Diode (D1) with the black stripes at the end corresponding to the line shown on the schematic symbol. Place it as shown in the schematic on the board in the correct position between tacks "B" and "C".

Step 11
Identify the capacitors (C1, C2) and place them in position. C1 goes between tacks "B" and "D", and C2 goes between "C" and "E".

Step 12
Take one of the alligator clip leads and wrap the end of the wire around tack "A". Wrap the end of the other alligator clip lead around tack "F". Make sure that you hammer these tacks down securely to prevent the alligator clip wires from pulling away from the tack causing loss of contact.

Step 13
Take bare copper wire and connect tacks "D", "E", and "F".

Step 14
When all of the components are arranged as desired, the tacks can be hammered into place. Now your radio is complete. Happy Listening!

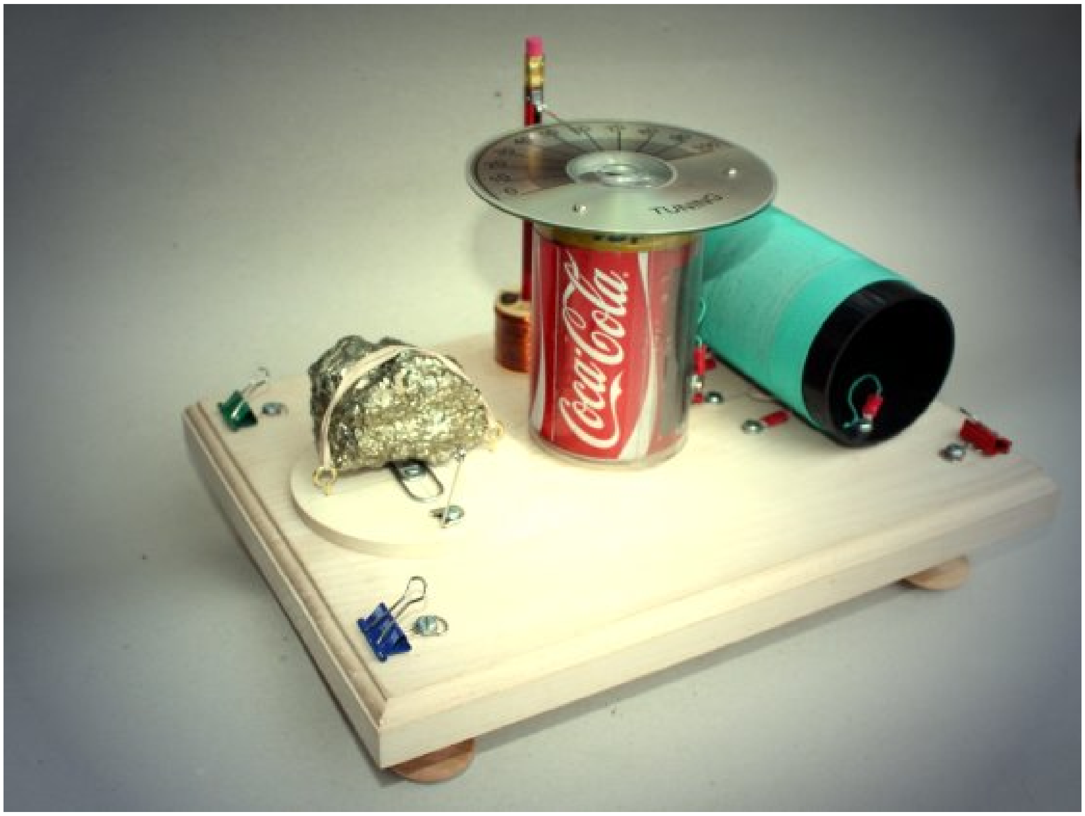
Trash Can Radio
with Fools Gold Detector



I wanted to make a radio that was very simple to construct so that anybody could make it from readily available materials and parts. I thought it may be useful if there was for example an emergency survival situation or the networks had broken down or you were marooned but really just a nice piece of fun to construct in the holidays. It really works and is quite listenable

This radio was made from what was basically around in any domestic house ie Paper clips pencil Cokacola can cotton reel curtain hooks an elastic band a safety pin and a breadboard. The only thing that was bought by me was some wire but this could have easily been obtained from an old broken down domestic appliance transformer ie from a microwave oven.

The most critical item to make was the main tuning coil this was wound on a 6 inch long by 3 inch diameter piece of drain pipe. I stuck to my old favorite circuit and type of coil. This is the' Mystery Crystal radio' circuit and coil (see link to constructional details below) . It is a very simple and very sensitive circuit and actually works better with a piece of Iron Pyrite (Fools Gold) than a crystal diode like the 1N34 . On the diode there was overlapping of stations but not so on the fools gold.

The main tuning capacitor was made from a cokacola can. I cut away half of the can area. I then stuck another piece of coke can onto a piece of clear plastic Christmas cake wrapper with double sided tape. This was then secured to a CD disc also with double sided tape. The whole thing was made to rotate on the can thus producing a crude but quite effective tuning capacitor The capacitance swing was from 100pf to 400pf. This enabled me to tune most of the medium wave band with ease.

The detector was made from a very large piece of iron pyrite and an elastic band two curtain hooks and a nickel plated safety pin all mounted on a disc of wood . I had not tried such a large piece of pyrite before in a detector but there seemed to be no deterioration of sensitivity due to size or positioning of the safety pin. I found the best part to just touch the pin on was not the flat faces of the crystal but the small crystaline structures or clusters. You do not need a firm pressure but just a light touch contact even just a resting position is the best. It is by no means as fiddly as the Galena type detectors and seems less prone to vibration.

All the set wiring was tucked away under the breadboard , there were only about half a dozen wires anyway. This was a nice little project and I really enjoyed making and listening to it over the Christmas holidays.

PCT™ PRE-CRYSTALLIZATION TEST

APPLICATION

- Determine the appropriate sample concentration for crystallization screening

FEATURES

- Conserve sample
- Optimize sample concentration prior to initial screens
- Provide insight to sample homogeneity

DESCRIPTION

The PCT Pre-Crystallization Test is used to determine the appropriate sample concentration for crystallization screening. Sample concentration is a significant crystallization variable. Samples too concentrated can result in amorphous precipitate, while samples too dilute can result in clear drops. Precipitate and clear drops are typical crystallization screen results for reagent conditions which do not promote crystallization and are part of every crystallization screen. However, by optimizing protein concentration for the screen, the number of clear and precipitate results can often be reduced, which in turn results in more efficient sample utilization while at the same time enhancing the chances for crystallization. PCT can minimize or prevent situations where a screen results in an over abundance of precipitate or clear drops.

The PCT kit contains 4 unique, preformulated, sterile filtered reagents used to evaluate protein concentration for crystallization screening. Initially, the sample protein is mixed with two of the reagents to determine if the protein concentration is appropriate for crystallization screening. If the protein is very sensitive to salt and polymer concentration, based on initial PCT results, the protein may be evaluated using a second set of PCT reagents. PCT results will then provide insight to either the appropriate sample concentration or indicate that other diagnostic testing such as native gel electrophoresis or dynamic light scattering should be performed to demonstrate sample homogeneity appropriate for crystallization.

Each PCT kit contains 4 unique reagents, 50 ml each. This kit is useful for researchers who already have crystallization plates and cover slides.

Each PCT kit (with plates) contains 4 unique reagents, 30 ml each, plus 24 well VDX™ Plates with sealant and plain cover slides. This kit is useful for labs without access to crystallization plates and cover slides.

INDEX™ • INDEX HT™

APPLICATION

- Primary, diverse reagent system crystallization screen for proteins, complexes, peptides, nucleic acids, & water soluble small molecules

FEATURES

- Developed at Hampton Research
- A data-driven biased sparse matrix and grid screen
- Screens classic, contemporary, & modern crystallization reagents
- Samples pH 3 to 9
- Compatible with microbatch, vapor diffusion, & liquid diffusion methods
- Specially formulated reagent zones:
  - Traditional salts versus pH
  - Neutralized organic acids
  - High [salt] with low [polymer]
  - High [polymer] with low [salt]
  - Low ionic strength versus pH
  - PEG & Salt versus pH
  - PEG & Salt
- Tube or Deep Well block format

SUCCESS STORY

Crystals of a diabetes related protein.

Courtesy of Allan D'Arcy and Aengus Mac Sweeney.

Morphochem AG

DESCRIPTION

Index is designed as a 96 reagent crystallization screen that combines the strategies of the grid, sparse matrix, and incomplete factorial screening with traditional, contemporary, and new crystallization reagent systems into a highly effective and efficient format.

Index, as the name implies, efficiently samples a series of specially formulated reagent zones to identify which reagent class or classes and pH are effective in producing crystals or limiting sample solubility. Results from Index can be used to design optimization experiments and to identify follow on screens by reagent class. For example, positive results with salt based reagent in Index may be followed up with further screening using SaltRx or Grid Screen Salt. Success with polymer based reagents in Index may be followed up with further screening using PEGRx or PEG/Ion.

Index utilizes a broad, yet refined portfolio of crystallization reagent systems. These include the following: (1) traditional salts such as Ammonium sulfate and Sodium chloride versus pH; (2) neutralized organic acids such as Sodium malonate and Tacsimate; (3) High salt concentration mixed with low polymer concentration as well as high polymer concentration mixed with low salt concentration and; (4) Low ionic strength using polymers such as PEG, MPD, Pentaerythritols versus pH. These reagent systems are formulated across a sparse matrix and incomplete factorial of concentration ranges, sampling a pH range of 3 to 9.

Index contains 96 unique reagents, 10 ml each.

Index HT contains 96 unique reagents in a single Deep Well block format.

Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics and buffers.

Measured pH range of kit is 3 to 9 at 25°C
Average measured pH of kit is 6.8 at 25°C
Median measured pH of kit is 6.9 at 25°C

CRYSTAL SCREEN™ • CRYSTAL SCREEN 2™ • CRYSTAL SCREEN HT™

APPLICATION

- Primary screen for proteins, soluble peptides, nucleic acids, & water soluble small molecules
- Sparse matrix additive screen

FEATURES

- The original sparse matrix screen
- Sparse matrix formula efficiently samples salts, polymers, organics, & pH
- Proven effective with more than 1,000 biological macromolecules
- Tube or DeepWell block format

SUCCESS STORY

Crystal of gp120, the exterior envelope glycoprotein of type 1 HIV. Preliminary crystallization conditions obtained using Crystal Screen from Hampton Research.

Courtesy of P.D. Kwong[1], R. Wyatt[2], E. Desjardins[2], J. Robinson[3], F.C. Culp[4], B.D. Hellmig[4], R.W. Sweet[4], J. Sodroski[2], and W.A. Hendrickson[1,5].

DESCRIPTION

The Crystal Screen and Crystal Screen 2 reagent kits are designed to provide a highly effective and rapid screening method for the crystallization of macromolecules. The screens are simple and practical for finding initial crystallization conditions. The initial crystallization conditions for more than 1,000 proteins, peptides, oligonucleotides, and small molecules have been determined using Crystal Screen.

A highly effective approach to overcome the exhaustive search for suitable crystallization conditions is the use of a sparse matrix method of trial conditions that is biased and selected from known crystallization conditions for macromolecules. The formulation utilized in Crystal Screen and Crystal Screen 2 evaluates 96 unique mixtures of pH, salts, polymers and organics, and their ability to promote crystal growth.

Crystal Screen contains 50 unique reagents, 10 ml each and is based on the sparse matrix formulation first described by Jancarik and Kim in 1991.

Crystal Screen 2, an extension of Crystal Screen, contains 48 unique reagents, 10 ml each and is based on the formulation first described by Cudney et al in 1994.

Crystal Screen HT contains 1 ml each of reagents 1-48 from Crystal Screen and all 48 reagents from Crystal Screen 2 in a single Deep Well block format.

Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics and buffers.

Order Information

Each Crystal Screen kit contains 50 unique reagents. Each Crystal Screen 2 kit contains 48 unique reagents. To order individual reagents, use Custom Shop™ catalog numbers listed below. Refer to page 36 for further details.

Cat. No.	Name	Description	Price
HR2-110	**Crystal Screen**	10 ml, tube format	**$285.00**
HR2-112	**Crystal Screen 2**	10 ml, tube format	**$285.00**
HR2-130	**Crystal Screen HT**	1 ml, Deep Well block format	**$185.00**
HR2-910-**	**Crystal Screen Custom Shop**	185 ml	**$138.00**
HR2-912-**	**Crystal Screen 2 Custom Shop**	185 ml	**$138.00**

** = reagent number 1-50 (for Crystal Screen)
** = reagent number 1-48 (for Crystal Screen 2)

APPLICATION

- Primary and secondary, polymer and pH based crystallization screen for biological macromolecules

FEATURES

- Developed at Hampton Research
- PEGRx 1 primary screen variables are polymer type (16 different polymers), polymer molecular weight, pH and low ionic strength.
- PEGRx 2 primary screen variables are polymer type (13 different polymers), polymer molecular weight, pH and secondary reagents which include additives, salts, volatile organics and polyols.
- PEGRx HT combines PEGRx 1 and PEGRx 2 in a single 96 Deep Well block
- pH range 3.5 - 9, using 10 different buffer systems
- Polymer molecular weight range 200 to 20,000
- Tube or Deep Well block format

DESCRIPTION

PEGRx is a primary and secondary, polymer and pH based crystallization screen developed at Hampton Research. It is designed to evaluate polymer based crystallization reagents and pH in low (PEGRx 1) to medium ionic strength (PEGRx 2). It is also designed for use as a secondary or optimization screen to follow the Hampton Research Index screen when polymer based reagents produce hits and interesting solubility leads.

PEGRx 1 is a crystallization reagent kit designed to evaluate an array of polymers of varying molecular weight in a low ionic strength environment versus a wide range of pH. Polymer reagents include Polyethylene glycols, Polyethylene glycol monomethylethers, and Jeffamines. The molecular weight range between 200 and 20,000 is evaluated in a low ionic strength formulation. Ten different buffers are used to span the range of pH between 3.5 and 9. The primary screen variables are polymer type, polymer molecular weight, pH and low ionic strength.

PEGRx 2 is a crystallization reagent kit designed to evaluate an array of polymers of varying molecular weight in a medium ionic strength environment in the presence of additives, salts, volatile organics and polyols versus a wide range of pH. Polymer reagents include Polyethylene glycols and Polyethylene glycol monomethylethers. The polymer molecular weight range between 200 and 20,000 is evaluated in a medium ionic strength formulation. Ten different buffers are used to span the range of pH between 3.5 and 9. The primary screen variables are polymer type, polymer molecular weight, pH and secondary reagents which include additives, salts, volatile organics and polyols.

PEGRx 1 contains 48 unique reagents, 10 ml each.

PEGRx 2 contains 48 unique reagents, 10 ml each.

PEGRx HT contains 1 ml of each reagent from PEGRx 1 and PEGRx 2 in a single Deep Well block format.

Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics and buffers.

Order Information

PEGRx 1 and PEGRx 2 kits each contain 48 unique reagents. To order individual reagents, use Custom Shop™ catalog numbers listed below. Refer to page 36 for further details.

PEG/ION SCREEN™ • PEG/ION 2 SCREEN™ • PEG/ION HT™

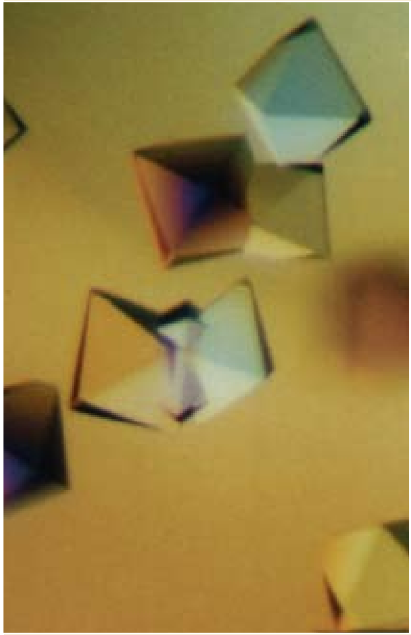
APPLICATION

- Primary or secondary, polymer, salt and pH matrix crystallization screen for biological macromolecules

FEATURES

- Developed at Hampton Research
- PEG/Ion is a sparse matrix profile of anions and cations in the presence of monodisperse Polyethylene glycol 3,350 over pH 4.5 - 9.2
- PEG/Ion 2 screens a complete profile of titrated organic acids at varying pH levels (3.7 - 8.8) in the presence of monodisperse PEG 3,350
- PEG/Ion HT combines PEG/Ion and PEG/Ion 2 in a single 96 Deep Well block
- Tube or Deep Well block format

SUCCESS STORY



Crystals of Proteinase K. Preliminary crystallization conditions obtained using PEG/Ion Screen from Hampton Research.

Crystals grown at Hampton Research.

DESCRIPTION

PEG/Ion, developed by Hampton Research, is a crystallization screen designed to evaluate monodisperse, high purity Polyethylene glycol 3,350 and 48 unique salts representing a very complete range of anions and cations frequently used in the crystallization of biological macromolecules. The primary screening variables are PEG, ion type, ionic strength, and pH. More than 60% of the published crystallizations utilized PEG as a primary crystallization reagent and in approximately 50% of those reports, the PEG was combined with an ion as a secondary crystallization reagent.

PEG/Ion 2 is an extension to the fundamental crystallization strategy in PEG/Ion. PEG/Ion 2 reagents cover the monodisperse, high purity Polyethylene glycol 3,350 and an array of neutralized and pH adjusted organic acids, multivalent ions, a novel Citrate BIS-TRIS propane buffer system and pH (4 - 8.8). The formulation of PEG/Ion 2 was developed at Hampton Research. Each of the 48 reagents in PEG/Ion 2 contains PEG 3,350 as the polymer (precipitant). The concentration of PEG is varied from 12% w/v to 20% w/v depending upon the type and concentration of buffer/salt paired with the polymer. Thirteen of the forty-eight PEG/Ion 2 reagents contain a separate buffer component. The remaining PEG/Ion 2 reagents are buffered by the titrated organic acid salt. Six of these thirteen conditions feature a novel Citric acid BIS-TRIS propane (CBTP) buffer. The CBTP buffer uses Citric acid and BIS-TRIS propane as the acid base pair to create a two component buffer system effective across pH 2.5 to 9.5. The ratio of Citric acid to BIS-TRIS propane determines the solution pH. Thirty-five of the forty-eight PEG/Ion 2 reagents contain a neutralized or pH adjusted organic acid in the presence of the polymer. Neutralized organic acids are highly effective crystallization salts.[1] Four PEG/Ion 2 reagents feature polyvalent cations. Two of these reagents contain cation mixes, saving sample by screening six different cations with only two reagents. Tryptone, a casein digest combinatorial library of peptides, is included in PEG/Ion 2.

PEG/Ion contains 48 unique reagents, 10 ml each.

PEG/Ion 2 contains 48 unique reagents, 10 ml each.

PEG/Ion HT contains 1 ml of each reagent from PEG/Ion and PEG/Ion 2 in a single Deep Well block format.

Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics and buffers.

PEG/Ion 2

Measured pH range of kit is 3.7 to 8.8 at 25°C
Average measured pH of kit is 6.4 at 25°C
Median measured pH of kit is 6.7 at 25°C
Mode measured pH of kit is 6.7 at 25°C

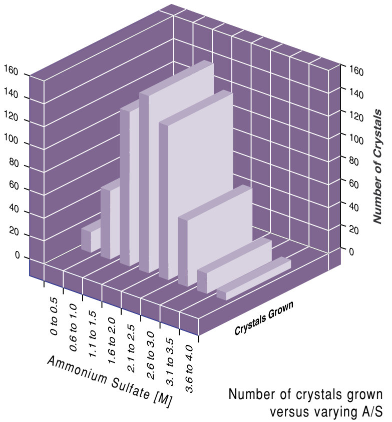
GRID SCREENS™ • QUIK SCREEN™

APPLICATION

- Primary or secondary, salt, polymer, organic and pH grid crystallization screen for biological macromolecules

FEATURES

- A systematic grid screen varying salt or polymer or organic versus pH
- Samples pH 4 to 9
- Combine reagents within or between screens to customize your screen
- Combine reagents between rows or columns to create expanded grid screens
- Tube or Deep Well block format



Number of crystals grown versus varying A/S concentrations [M]

DESCRIPTION

Grid Screen
HR2-211

Grid Screen Salt HT™ combines Grid Screen Ammonium Sulfate, Grid Screen Sodium Malonate, Quik Screen and Grid Screen Sodium Chloride into a single 96 Deep Well block format. The block contains 1 ml of each reagent.

Grid Screen Ammonium Sulfate systematically evaluates Ammonium sulfate at four concentrations (0.8, 1.6, 2.4, 3.2 M) versus 6 pH levels (4, 5, 6, 7, 8, 9).

Grid Screen Sodium Malonate evaluates Sodium malonate at six concentrations (1.0, 1.5, 1.9, 2.4, 2.9, 3.4 M) versus four pH levels (4, 5, 6, 7).

Quik Screen evaluates Sodium potassium phosphate at four concentrations (0.8, 1.0, 1.4, 1.8 M) versus six pH levels (5.0, 5.6, 6.3, 6.9, 7.5, 8.2).

Grid Screen Sodium Chloride evaluates Sodium chloride at four concentrations (1.0, 2.0, 3.0, 4.0 M) versus six pH levels (4, 5, 6, 7, 8, 9).

Grid Screen PEG 6000 evaluates Polyethylene glycol at four concentrations (5, 10, 20, 30 %w/v) versus six pH levels (4, 5, 6, 7, 8, 9).

Grid Screen MPD evaluates MPD at four concentrations (10, 20, 40, 65 %v/v) versus six pH levels (4, 5, 6, 7, 8, 9).

Grid Screen PEG/LiCl evaluates Polyethylene glycol at four concentrations (0, 10, 20, 30 %w/v) in the presence of 1.0 M Lithium chloride versus six pH levels (4, 5, 6, 7, 8, 9).

Grid Screens and Quik Screen each contain 10 ml of 24 unique reagents.

Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics and buffers.

SALTRX 1™ • SALTRX 2™ • SALTRX HT™

APPLICATION

- Primary or secondary, salt and pH matrix crystallization screen for biological macromolecules

FEATURES

- Developed at Hampton Research
- Salt versus pH matrix crystallization screen
- Samples pH 4 - 9
- 22 unique salts versus salt concentration and pH
- Compatible with microbatch, vapor diffusion, liquid & gel diffusion methods
- Preformulated, ready to screen
- All salts and buffers in screen readily available as Optimize reagents for reproducing and optimizing crystals
- Tube or Deep Well block format

SUCCESS STORY

Crystals grown using SaltRx, reagent 62. They were grown using the Cyberlab C240 robot and the Neuro Probe plate. These were grown just in time to freeze and take to the synchrotron (no time for optimizations). MAD data were collected on these crystals and the structure has been solved to 2.3Å resolution.

Courtesy of Annie Hassell.

GlaxoSmithKline

DESCRIPTION

SaltRx was developed by Hampton Research as a primary and secondary, salt and pH based crystallization screen for biological macromolecules. Salt is the only primary crystallization reagent (precipitant) utilized. Based on a design of 96 conditions, the screen evaluates a broad portfolio of crystallization salts of varying concentration and pH. The selection, concentration, and pH of the salts were determined by data mining the BMCD[1] and other crystallization databases, crystallization reports in the literature, and internal crystallization trials performed at Hampton Research. Based on this analysis, up to 35% of protein crystallizations involve salt as the primary crystallization reagent.

SaltRx can be used as a primary crystallization screen when salt, ionic strength and pH are desired or suspected as appropriate crystallization variables. It is also useful as a secondary screen when salt based reagents/conditions from screens such as Index, Crystal Screen, and Grid Screen produce crystals and when further screening for additional salt conditions or optimization is desired.

SaltRx is designed to be used as a 96 reagent screen.

SaltRx 1 contains 48 unique reagents, 10 ml each.

SaltRx 2 contains 48 unique reagents, 10 ml each.

SaltRx HT contains 1 ml of each reagent from SaltRx 1 and SaltRx 2 in a single Deep Well block format.

Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics and buffers.

MEMBFAC™ • CRYSTAL SCREEN LITE™ • MEMBFAC HT™

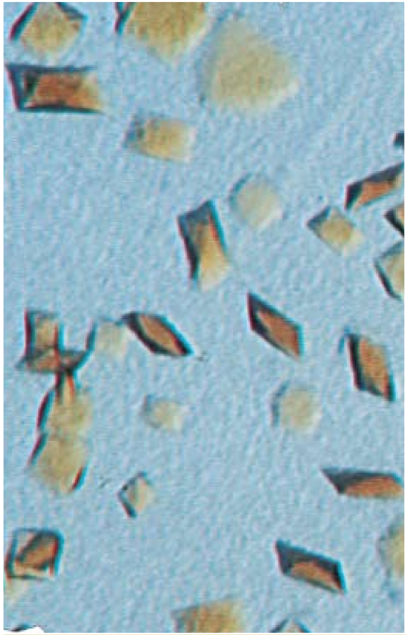
APPLICATION

- Primary sparse matrix crystallization screen for membrane proteins and samples with limited solubility

FEATURES

- Membrane protein sparse matrix screens[1]
- Sparse matrix formula efficiently samples salts, polymers, organics and pH
- pH range 4.6 - 8.5
- Formulated for use with detergents
- Crystal Screen Lite features a lower ionic strength than the original Crystal Screen
- Tube or Deep Well block format

SUCCESS STORY



Crystals above are those of the membrane protein succinate:quinone oxireductase. Preliminary crystallization conditions determined using MembFac.

Courtesy of Michael Stowell.

MRC-LMB

DESCRIPTION

MembFac is a highly effective sparse matrix screen specifically designed as a preliminary screen for the crystallization ofmembrane proteins. MembFac is based upon the highly effective biased sparse matrix methodology. The MembFac screen matrix is optimized for the crystallization of membrane proteins.

MembFac contains 48 unique reagent formulations. With this set of 48 conditions, numerous chemicals and chemical combinations are utilized, allowing one to evaluate a large variety of potential crystallization conditions. MembFac covers a broad pH range between 4 and 9.

The Rationale

The basic rationale of MembFac is to perform a sparse matrix screen while changing the detergent dimension because detergents play an important factor in the crystallization of membrane proteins. A MembFac screen is to be completed for each detergent. Detergent screens are available separately.

The Method

The membrane protein of interest is first isolated in the detergent which gives the highest stability and activity. The protein concentration should be approximately 10 to 20 mg/ml and the detergent concentration should be only slightly above the CMC. The sample is then set against MembFac, using all 48 solutions plus the screening detergent(s) of choice. The screening detergent concentration should be approximately one to three times the CMC. Hence, for each detergent screened, one would utilize approximately 1 to 2 mg of sample.

The MembFac protocol was used to crystallize membrane proteins including SQR, fumerate: quinone oxireductase, LHII, and LHCII.

Crystal Screen Lite is a sparse matrix of trial crystallization reagent conditions based upon the Crystal Screen™.[3] The primary screen variables are salt, pH, and precipitant (salts, polymers, volatile organics, and non-volatile organics).[2] Crystal Screen Lite differs from the original Crystal Screen kit in that the primary precipitant reagents are one-half the concentration of that used in the original Crystal Screen formulation. The secondary salts, ions, and buffers remain at the original Crystal Screen concentration. Reducing the primary concentration of the primary precipitant results in a screen which is “more gentle” on the sample and typically produces much less precipitate conditions than the original Crystal Screen.

MembFac contains 48 unique reagents, 10 ml each.

MembFac HT contains 1 ml each of all 48 reagents from MembFac and reagents 1-48 from Crystal Screen Lite in a single Deep Well block format.

Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics and buffers.

NATRIX™

APPLICATION

- Crystallization screen for nucleic acids & protein/nucleic acid complexes

FEATURES

- Nucleic acid sparse matrix screen[1]
- Sparse matrix formula efficiently samples salts, polyols, organics, & pH
- pH range 5.6 - 8.5
- Screen Magnesium, Potassium, & Ammonium anions

SUCCESS STORY

Crystal of MtaN, the N-terminal DNA binding domain of the Multidrug Transporter Activation protein from B. subtilis. Initial crystals grown from Natrix reagent number 29.

Courtesy of Michael Godsey.

Oregon Health Sciences University, Dept. of Biochemistry and Molecular Biology

DESCRIPTION

Natrix is based upon a published protocol which is highly effective for the crystallization of nucleic acids and protein-nucleic acid complexes. A variety of hammerhead ribozymes and other ribozymes, RNAs, DNAs, RNA-drug complexes, and RNA-protein complexes have been crystallized using the Natrix protocol.

By using sparse matrix sampling technology, Natrix allows one to quickly test wide ranges of pH, salts, and precipitants using a very small sample (50 to 100 μl) of nucleic acid.

Natrix is unique in that rather than relying solely on the traditional nucleic acid precipitant MPD, Natrix also utilizes Polyethylene glycols (PEGs) in a variety of molecular weights (200, 400, 4,000, 8,000) as well as 2-Propanol, Polyethylene glycol monomethyl ether (PEG MME), and 1,6-Hexanediol. Many of the polymeric and low molecular weight organic precipitants are combined with various monovalent salts as precipitating agents. This combination of salts and low molecular weight organics and polyalcohols, as well as the utilization of varying chain length PEGs, has proven to be a successful combination for producing nucleic acid and protein-nucleic acid complex crystals.

RNA Crystallization

Typical crystallization trials using Natrix will use the hanging or sitting drop methodology. Sample preparation is straightforward. The highly purified sample is heated to 75°C and annealed in the presence of the appropriate polyamine and buffer. After cooling to room temperature, the sample is mixed with an equal amount of Natrix solution and set against a reservoir containing the same Natrix solution for vapor diffusion equilibration. Typically, crystals are observed within the first week of setting up the trial.

Each Natrix contains 48 unique reagents of varying salt and precipitant composition over six different pH levels. Each preformulated, sterile filtered solution provides sufficient reagent for more than a dozen screens. The method is suitable for hanging drop, sitting drop, sandwich drop, and microbatch crystallization methodologies. Crystallization plates are sold separately. Natrix does not include polyamines. It is recommended that a polyamine such as Spermine be added to the sample prior to screening and that various polyamines be screened AFTER preliminary crystallization conditions have been determined.

Each Natrix kit contains 48 unique reagents, 10 ml each. Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics, and buffers.

CRYSTAL SCREEN CRYO™

APPLICATION

- Crystallization screen for proteins, peptides, & nucleic acids

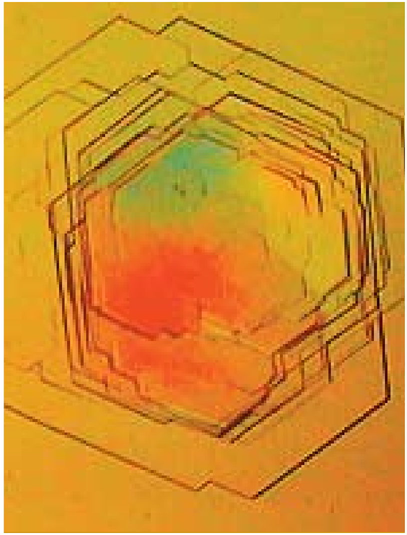
FEATURES

- Cryo ready reagents for cryocrystallography[1]
- Sparse matrix formula efficiently samples salts, polymers, organics, & pH

METHODOLOGIES

- Screen for cryo and crystallization conditions using only one screen

SUCCESS STORY



The protein crystal above is a LFA-1 I-domain/Inhibitor complex. Crystallization conditions obtained using Crystal Screen Cryo from Hampton Research.

DESCRIPTION

The proportion of macromolecular x-ray structures solved using cryocrystallographic methods is increasing at an exponential rate. The advantages of macromolecular cryocrystallography are numerous. The most widely used method of flash cooling macromolecular crystals is to support the crystal in a film of cryoprotected mother liquor on or in a small fiber loop which is subsequently cooled in liquid nitrogen at around 100°K. The liquid about the crystal must freeze as an amorphous glass to avoid crystal damage and diffraction from ordered ice. Cryoprotection is achieved by mixing the mother liquor and crystal with a suitable cryoprotectant reagent. The most frequently utilized cryoprotectant is glycerol.

Determining a Cryoprotectant

Determining initial and optimal cryoprotectant concentration is often a process of trial and error. One must find suitable cryoprotectant concentrations which stabilize the crystal while at the same time combine with the crystallization reagent to form an amorphous glass.

Crystal Screen Cryo removes the guesswork from determining the preliminary glycerol concentration required to mix with the crystallization reagent to form an amorphous glass. Crystal Screen Cryo reagents are preformulated with the appropriate amount of glycerol required to form an amorphous glass with each unique reagent composition. Crystals obtained in Crystal Screen Cryo will already have a suitable concentration of glycerol in the reagent. This avoids exhaustive empirical searches for preliminary cryoprotectant conditions. From the preliminary cryoprotectant conditions, cryoprotectant concentration can be optimized to minimize mosaic spread and maximize diffraction resolution.

Crystal Screen Cryo is a complete sparse matrix reagent kit designed to provide a rapid screening method for the crystallization of biological macromolecules in the presence of glycerol, the most frequently utilized cryoprotectant. Crystal Screen Cryo utilizes the original Crystal Screen™ protocol but is optimized to include the appropriate concentration of glycerol required to form an amorphous glass at 100°K. The primary screen variables are salt, pH, precipitant (salts, polymers, volatile organics, and non-volatile organics), and cryoprotectant concentration. The screen is a straightforward, effective, and practical kit for determining preliminary crystallization conditions and provides a good starting point for finding suitable cryoprotectant conditions for macromolecular crystals grown in a wide range of reagents. Crystal Screen Cryo is also effective in determining the solubility of a macromolecule in a wide range of precipitants and pH.

Each Crystal Screen Cryo kit contains 50 unique reagents, 10 ml each. Ready-to-use reagents are sterile filtered and formulated with ultra-pure Type 1 water, using the highest purity salts, polymers, organics, and buffers.

NUCLEIC ACID MINI SCREEN™

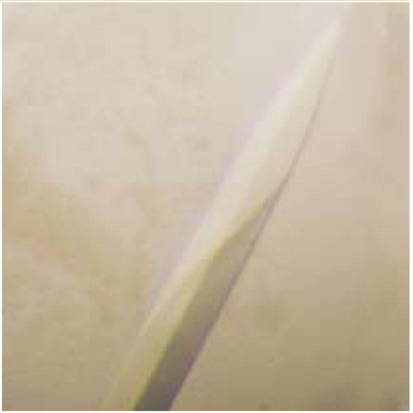
APPLICATION

- Crystallization screen for nucleic acid fragments

FEATURES

- Screen a matrix of pH, polyamine, & ions
- Can be used with ribozymes, pseudoknots, RNA, & DNA
- Uses MPD as the primary precipitant

SUCCESS STORY



Crystal of RNA tetraloop.

Courtesy of Imre Berger and Li Su. MIT

DESCRIPTION

NUCLEIC ACID MINI SCREEN™
Nucleic Acid Crystallization Kit
HAMPTON RESEARCH

The Nucleic Acid Mini Screen is an efficient screen formulated to assist in the determination of preliminary crystallization conditions of nucleic acid fragments.[1] The formulation is based upon the publication, "A Highly Efficient 24 Condition Matrix for the Crystallization of Nucleic Acid Fragments" where the preliminary crystallization conditions of 35 nucleic acids were determined utilizing this formulation.[1] Samples include DNA-Drug complexes, C-Tetrad and G-Quartet Motifs, RNA oligomers, and others. By using 1 to 4 mM oligonucleotide stock concentration, the screen requires less than 100 µl of sample. The screen is typically performed at 4°C although room temperature incubations can also be performed. To evaluate the effect of equilibration kinetics as well as initial and final sample concentrations, the screens are typically performed using the hanging or sitting drop vapor diffusion method with two drops on a slide (1 µl + 2 µl and 2 µl + 2 µl), side by side. The 24 well format of the mini screen provides for a fast setup and uses small amounts of sample. This makes it possible to cost-effectively screen many sequences as well as variations of a particular sequence. The composition of the Nucleic Acid Mini Screen allows one to apply the formulation to other nucleic acids such as deoxy- and ribozymes, pseudoknots, and tRNAs.

Each Nucleic Acid Mini Screen kit contains 24 unique reagents, 1.0 ml each plus a 250 ml volume of dehydrant (35% v/v MPD). All solutions are sterile filtered and formulated with ultra-pure Type 1 water.

LOW IONIC STRENGTH SCREEN™

APPLICATION

- Crystallization screen for intact monoclonal antibodies, monoclonal antibody fragments, & proteins less soluble at low ionic strength

FEATURES

- Screen a complete pH profile (2-12) at low ionic strength
- Enhanced temperature effects due to low ionic strength
- Monodisperse PEG 3350

Low Ionic Strength Screen Components

Buffer

DESCRIPTION

Low Ionic Strength Screen™
Crystallization Kit
HAMPTON RESEARCH

The Low Ionic Strength Screen is effective for determining the preliminary crystallization conditions of intact monoclonal antibodies[1]. However, this screen is not just an intact antibody screen. The screen has effectively determined the preliminary crystallization conditions for numerous monoclonal antibody fragments as well as other soluble proteins. The screen should be utilized as a low ionic strength crystallization screen for proteins where this strategy could be effective in determining preliminary crystallization screens.

In this screen, the concentration of a high purity, monodisperse PEG 3,350 is varied from 4 to 24% w/v (4, 8, 12, 16, 20 and 24% w/v) versus a pH range of 2 to 12 (2, 3, 3.5, 4, 4.5, 5, 5.5, 6.0, 6.5, 7, 7.5, 8, 8.5, 9, 9.5, 10, 11, 12). Stock buffer concentrations are 50 mM. Final buffer concentration in the drop is typically 10 mM.

Unique features of this screen: (1) Low ionic strength. Buffer concentration is supplied as 50 mM, resulting in an initial drop concentration of 10 mM (Drop = 4 μl sample, 2 μl buffer, 5 μl precipitant); (2) The Polyethylene glycol (PEG) 3,350 is a special, high-purity, monodisperse preparation with an Mr of 3300-3400. Most PEGs of this molecular weight have an Mr of plus or minus 500 rather than 50; (3) An extremely broad range of pH 2 to 12 is sampled. At low ionic strength, the effects of pH and temperature upon sample solubility are amplified. Hence this screen allows one to critically evaluate the effects of temperature and pH upon sample solubility and crystallization. It is recommended the screen be repeated at several temperatures between 4°C and 37°C to take advantage of the low ionic strength feature.

The format of this screen is different than other screens offered by Hampton Research. The screen is supplied as a set of eighteen 50 mM buffers, six PEG 3,350 concentrations, and a single dehydrant, PEG 3,350. This formulation allows one to screen up to 108 conditions if desired. The formulation is designed to offer options. Coarse sample of pH and/or precipitant concentration can be performed with 24 or even 12 drops. This will eliminate large regions of sampling space and conserve sample. Subsequent screens and perhaps even optimization can encompass an increasingly finer grid matrix of pH, precipitant concentration, as well as other variables significant for sample crystallization. The protocol requires the following pipetting steps for a typical vapor diffusion experiment: (1) Pipet dehydrant to reservoir; (2) Pipet drop; (3) Pipet buffer to drop; (4) Pipet precipitant to drop.

Each kit contains 24 unique reagents of varying pH and PEG 3,350 concentration. Buffers of 50 mM are supplied for pH 2, 3, 3.5, 4, 4.5, 5, 5.5, 6, 6.5, 7, 7.5, 8, 8.5, 9, 9.5, 10, 11, and 12 in 1 ml volumes. The precipitant Polyethylene glycol 3,350 is supplied as 4, 8, 12, 16, 20, and 24% w/v in 1 ml volumes. Dehydrant is supplied as 250 ml of 24% PEG 3,350. Combining each pH and precipitant supplied can generate 108 crystallization screening conditions. All solutions are sterile filtered and formulated with ultra-pure Type 1 water.

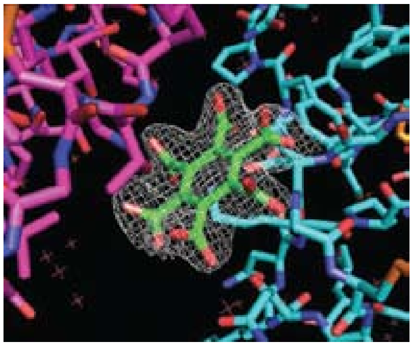
SILVER BULLETS™ • SILVER BULLETS BIO™

APPLICATIONS

- Primary, secondary or orthoganol crystallization screen for biological macromolecules
- For use with soluble proteins and membrane proteins
- A methodology to uncover different crystal forms
- Optimization screening in conjunction with preliminary crystallization conditions
- ThermoFluor® assays
- Solubility, folding and stability studies

FEATURES

- Developed at Hampton Research
- Screens a portfolio of small molecules for their ability to establish stabilizing, intermolecular, hydrogen bonding, hydrophobic and electrostatic interactions which could promote lattice formation and crystallization
    - Organic salts & acids
    - Biologically active small molecules
    - Amino acids and peptide
    - Macromolecular digests
- Modular screen design allows Silver Bullets to be screened against virtually any crystallization reagent
- Original & Bio Formulations
- A combinatorial library of more than 1,090 chemicals, of which more than 400 are unique
- Tube or Deep Well block format



Mellitic acid, a Silver Bullet for Trypsin

DESCRIPTION

An alternative approach to macromolecular crystallization. The Silver Bullets formulation and methodology screens validated small molecule libraries against a few select crystallization reagents as an effective, orthogonal approach to macromolecular crystallization. The formulation offers an alternative and efficient approach that is an excellent complement to current crystallization method-ologies.

Silver Bullets is a library of small molecules that have been shown to promote crystal lattice formation. X-ray diffraction analysis has demonstrated the reagents have the ability to:

- Stabilize the conformation of the protein
- Perturb the interaction of the protein with the solvent
- Participate in forming important lattice contacts
- Build the crystal lattice by forming reversible cross-links between the macromolecules in the crystal

Results with the Silver Bullets approach have been very encouraging, with more than twice as many proteins being crystallized overall as were crystallized from controls free of any small molecules.[1-3] There have been frequent occasions where some exceptional result has been obtained for specific proteins, and numerous examples where new or unusual crystal forms were obtained. X-ray diffraction analysis has revealed the small molecules in the crystal lattice, involved at the centers of hydrogen bonding networks and electrostatic interaction.[3]

Silver Bullets can be used as a primary crystallization screen; as a secondary or orthogonal screen to produce crystals when traditional screens are not successful; as an optimization screen in conjunction with preliminary crystallization conditions; as a methodology to uncover different crystal forms; to promote intramolecular interactions that may stabilize a macromolecules conformation and promote crystallization. Silver Bullets solutions are designed for use with the Silver Bullets PEG/Tacsimate Crystallization Reagents but may also be used with other crystallization reagents.

The Silver Bullets kits are composed of 96 solutions in either screw cap tubes or a single Deep Well block (Greiner 786261) HT format. Each reagent is a mixture of small molecules or macromolecular digest in 0.02 M HEPES sodium pH 6.8 buffer. Each Silver Bullets solution is supplied in a 0.25 ml volume. Each solution contains between 2 and 20 small molecules. Silver Bullets reagents include: Organic salts and acids • Biologically active molecules • Amino acids and peptides • Macromolecular digests. Silver Bullets Bio reagents include: Small organic molecules, organic salts, and organic acids • Biologically active molecules, co-factors, and ligands • Amino acids, peptides, nucleotides, drugs, and carbohydrates • Biochemical pathway intermediates.

University of Texas Southwestern Medical Center

DESCRIPTION

Additive Screen

Additive Screen is a library of small molecules that can affect the solubility and crystallization of biological macromolecules, including both soluble and membrane proteins. These small molecules can perturb and manipulate sample-sample and sample-solvent interactions, as well as perturb water structure which can alter and improve both the solubility and crystallization of a sample. Additives can stabilize or engender conformity by specific interaction with the macromolecules. There are numerous reports of the use of additives to improve the quality and size of macromolecular crystals.[1-5]

Additive Screen contains 96 unique reagents, 1 ml each, tube format.

Additive Screen HT contains 96 unique reagents, 1 ml each, in a single Deep Well block format.

DETERGENT SCREEN™ • DETERGENT SCREEN HT™

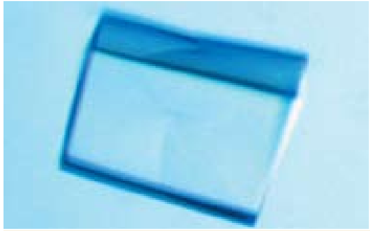
APPLICATION

- Prevent and manipulate non-specific aggregation due to hydrophobic interactions

FEATURES

- Kits include popular detergents used in the crystallization of membrane proteins
  - Ionic detergents
  - Non-ionic detergents
  - Zwitterionic detergents
  - Non-detergent Sulfobetaines
  - Synthetic lipids
- Useful with soluble proteins where hydrophobic interactions limit sample solubility
- Detergents are compatible with microbatch under oil crystallization, as well as vapor diffusion, free interface diffusion, & dialysis

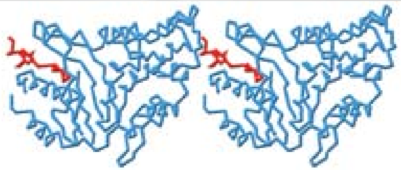
SUCCESS STORY



Crystal above is that of ß-Lactamase. Crystal was grown using 15% w/v PEG 6000, 50 mM HEPES pH 7.0, and in the presence of CYMAL-5 and CYMAL-6 detergent from the Hampton Research Detergent Screen kit 1.

Courtesy of James Knox.
University of Connecticut,
Department of Molecular and Cell Biology

DESCRIPTION



Detergent molecule interacting with beta-lactamase.

Detergent Screen kits are designed to allow the rapid and convenient evaluation of 96 unique detergent reagents for their ability to influence the solubility and crystallization of the sample. These screens are designed to be compatible with most popular crystallization reagents.

The detergents in these kits are capable of manipulating hydrophobic sample-sample interactions which can lead to non-specific aggregation, and prevent or interfere with sample crystallization. The detergents also perturb water structure which may play a role in sample crystallization.

Non-specific aggregation is a common deterrent to the crystallization of soluble macromolecules as well as membrane proteins. There is extensive literature demonstrating the effectiveness of including detergents in the crystallization trial towards preventing non-specific aggregation due to hydrophobic interactions and hence improving crystallization.[1] The kits allow one to screen the most effective detergents used in crystal growth.

The Detergent Screen kits are preformulated so that simple pipetting is all that is required to screen the detergents with the hanging or sitting drop vapor diffusion technique. Screens with these kits are usually performed after preliminary crystallization conditions have been determined, although ab initio screens are also practical. The kits are recommended for both soluble and membrane proteins where non-specific aggregation is a suspected complication or where one simply wishes to screen detergents as an optimization variable. The screens are suitable for hanging drop, sitting drop, microbatch, free interface diffusion and sandwich drop crystallization methodologies.

Each Detergent Screen kit contains 96 unique reagents. 0.25 ml of detergent solution is preformulated at 10 times the reported CMC (unless otherwise noted) in sterile filtered water.

HEAVY ATOM SCREENS

APPLICATION

- Heavy atoms for multiple isomorphous replacement

FEATURES

- Convenient sets of popular heavy atoms
- Each kit includes a heavy atom tutorial and formulation guide

DESCRIPTION

Heavy Atom Screen Pt
Multiple Isomorphous Replacement

A Heavy Atom Screen kit provides 50 mg of each heavy atom in an o-ring screw cap micro tube. This convenient format provides sufficient material for the preparation of numerous (15 x 100 mM or 1,500 x 1 mM) small volume (100 μl) fresh stock solutions of heavy atoms. The quantity is sufficient for screening and derivatization but avoids the problem of storing large quantities of heavy atoms. Individual heavy atoms from each kit are available in larger quantities on a special order basis for researchers requiring larger amounts of material.

SUCCESS STORY

Protein crystal with the heavy atom derivative Potassium osmate.

Kimberly J. Skinner, Structural Biology and Biophysics, Pfizer Global R&D, Sandwich, Kent, United Kingdom.

Heavy Atom Screen Pt (Platinum)

1. Potassium tetrachloroplatinate(II)
2. Ammonium tetrachloroplatinate(II)
3. Potassium hexachloroplatinate(IV)
4. Potassium tetranitroplatinate(II)
5. Potassium tetracyanoplatinate(II) hydrate
6. Dichloro(ethylenediamine)platinum(II)
7. Diammino Platinum Dinitrite
8. Potassium tetrabromoplatinate(II)
9. Potassium hexabromoplatinate(IV)
10. Platinum potassium iodide
11. Platinum potassium thiocyanate
12. Di-μ-iodobis(ethylenediamine)diplatinum(II) nitrate

Order Information

Each Heavy Atom Screen Pt kit contains 12 unique reagents. To order individual reagents, use Custom Shop™ catalog number listed below. Refer to page 36 for further details.

Cat. No.	Name	Description	Price
HR2-442	**Heavy Atom Screen Pt**	50 mg, tube format	**$418.00**
HR2-442-**	**Heavy Atom Screen Pt Custom Shop**	100 mg	**$80.00**

** = reagent number 1-12

Heavy Atom Screen Au (Gold)

1. Gold(I) potassium cyanide
2. Potassium tetrachloroaurate(III) hydrate
3. Sodium tetrachloroaurate(III) dihydrate
4. Gold(III) chloride
5. Hydrogen tetrachloroaurate(III) trihydrate
6. Potassium tetrabromoaurate(III) dihydrate

Order Information

Each Heavy Atom Screen Au kit contains 6 unique reagents. To order individual reagents, use Custom Shop™ catalog number listed below. Refer to page 36 for further details.

Cat. No.	Name	Description	Price
HR2-444	**Heavy Atom Screen Au**	50 mg, tube format	**$275.00**
HR2-444-**	**Heavy Atom Screen Au Custom Shop**	100 mg	**$80.00**

** = reagent number 1-6

Heavy Atom Screen Hg (Mercury)

1. Mersalyl acid
2. Ethyl Mercuric Phosphate
3. Mercury(II) chloride
4. Mercury(II) acetate
5. Ethylmercurithiosalicylic acid, sodium salt
6. Phenylmercury acetate
7. Mercury(II) potassium iodide
8. p-Chloromercuribenzoic acid
9. Ethylmercury chloride
10. Mercury(II) bromide
11. Mercury(II) iodide
12. Mercury(II) nitrate monohydrate
13. Mercury(II) cyanide
14. Mercury(II) oxide, yellow
15. Tetrakis(acetoxymercuri)methane

Order Information

Each Heavy Atom Screen Hg kit contains 15 unique reagents. To order individual reagents, use Custom Shop™ catalog number listed below. Refer to page 36 for further details.

Cat. No.	Name	Description	Price
HR2-446	**Heavy Atom Screen Hg**	50 mg, tube format	**$314.00**
HR2-446-**	**Heavy Atom Screen Hg Custom Shop**	100 mg	**$80.00**

** = reagent number 1-15

Heavy Atom Screen M1

1. Thallium(III) chloride hydrate
2. Thallium(I) chloride
3. Thallium(III) acetate hydrate
4. Lead(II) acetate trihydrate
5. Lead(II) nitrate
6. Lead(II) chloride
7. Silver nitrate
8. Cadmium chloride hydrate
9. Cadmium iodide
10. Potassium hexachloroiridate(IV)
11. Iridium(III) chloride hydrate
12. Sodium hexachloroiridate(III) hydrate
13. Ammonium hexachloroiridate(III) hydrate
14. Potassium hexanitroiridium(III)
15. Potassium osmate(VI) dihydrate
16. Ammonium hexabromoosmate(IV)
17. Potassium hexachloroosmate(IV)
18. Osmium(III) chloride hydrate
19. Acetoxytrimethyllead(IV)

Order Information

Each Heavy Atom Screen M1 kit contains 19 unique reagents. To order individual reagents, use Custom Shop™ catalog number listed below. Refer to page 36 for further details.

Cat. No.	Name	Description	Price
HR2-448	**Heavy Atom Screen M1**	50 mg, tube format	**$343.00**
HR2-448-**	**Heavy Atom Screen M1 Custom Shop**	100 mg	**$80.00**

** = reagent number 1-19

Heavy Atom Screen M2

1. Sodium tungstate dihydrate
2. Ammonium tetrathiotungstate(VI)
3. Samarium(III) chloride hexahydrate
4. Samarium(III) acetate hydrate
5. Samarium(III) nitrate hexahydrate
6. Lanthanum(III) nitrate hexahydrate
7. Europium(III) nitrate hexahydrate
8. Europium(III) chloride hexahydrate
9. Gadolinium(III) chloride hydrate
10. Lutetium(III) chloride hexahydrate
11. Lutetium(III) acetate hydrate
12. Ytterbium(III) chloride hydrate
13. Dysprosium(III) chloride hexahydrate
14. Praseodymium(III) chloride heptahydrate
15. Neodymium(III) chloride hydrate
16. Holmium(III) chloride hexahydrate
17. Potassium hexachlororhenate(IV)
18. Potassium perrhenate

Order Information

Each Heavy Atom Screen M2 kit contains 18 unique reagents. To order individual reagents, use Custom Shop™ catalog number listed below. Refer to page 36 for further details.

Cat. No.	Name	Description	Price
HR2-450	**Heavy Atom Screen M2**	50 mg, tube format	**$320.00**
HR2-450-**	**Heavy Atom Screen M2 Custom Shop**	100 mg	**$80.00**

** = reagent number 1-18

I3C PHASING KIT™

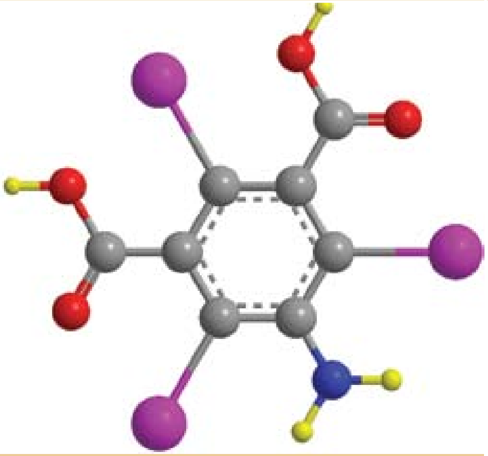
APPLICATION

- Produce heavy atom derivative of biological macromolecules for phasing

FEATURES

- I3C kit for soaking or cocrystallization
- Phasing using SAD or SIRAS
- Ready-to-use, no weighing required

DESCRIPTION



I3C can be used for heavy atom derivatization of biological macromolecules for subsequent single wavelength anomalous dispersion (SAD) or single isomorphous replacement plus anomalous scattering (SIRAS).

The two carboxylic acid groups and one amino group of I3C can interact by way of hydrogen bonds with both the backbone and side chains of proteins. This can result in a relatively highoccupancy of the bound ligand I3C. The three iodine atoms per I3C molecule provide for a strong anomalous signal.

The three iodine atoms in I3C form an equilateral triangle with 6.0 Å side lengths. These triangular structures can readily be identified in the anomalous electron density map.

Kit Contents
- 12 aliquots of I3C (280 mg each) (5-Amino-2,4,6-triiodoisophthalic acid CAS number 35453-19-1)
- 12 aliquots of 2.0 M Lithium hydroxide (650 μl each)
- User Guide

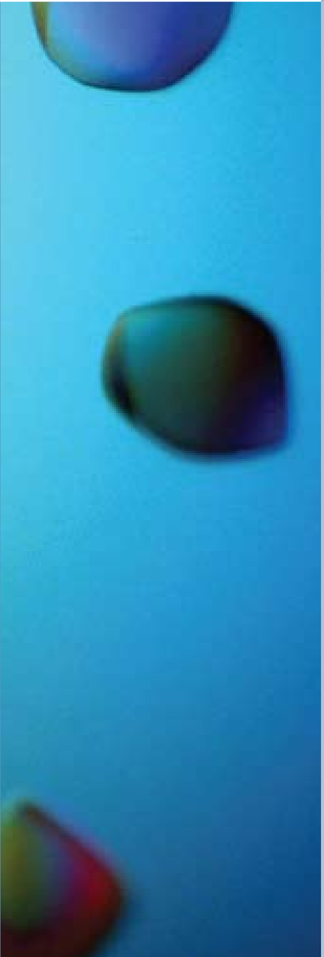
HAMPTON RESEARCH



CUSTOM SHOP™ CRYSTALLIZATION REAGENTS

DESCRIPTION

The Hampton Research Custom Shop delivers ready-to-use crystallization reagents for screening, optimizing and producing crystals. The reagents are formulated at the time of order, using the same production protocol, chemicals, and quality control used when making the original Hampton Research crystallization kit.

Formulating the Custom Shop reagents at the time of order ensures consistency as well as saves time and offers convenience. They are shipped within 48 hours. Custom Shop reagents may not be returned for refund or exchange.

To order Custom Shop reagents, use the catalog numbers listed below. If you have any questions, please feel free to contact Customer Service.

When reproducing and optimizing reagent conditions, please be sure to also consider the Hampton Research Optimize™ and StockOptions™ reagents and kits.

Additive Screen - 1.0 ml **$65.00**
Catalog Number: HR2-428-**
** = reagent number 1-96
For example, reagent number A1 = HR2-428-01

Catalog Number: HR2-930-**
** = reagent number A1-D6
For example, reagent number A1 = HR2-930-A1

Grid Screen PEG 6000 - 185 ml **$138.00**
Catalog Number: HR2-926-**
** = reagent number A1-D6
For example, reagent number A1 = HR2-926-A1

Grid Screen PEG/LiCl - 185 ml **$138.00**
Catalog Number: HR2-928-**
** = reagent number A1-D6
For example, reagent number A1 = HR2-928-A1

Grid Screen Sodium Chloride - 185 ml **$138.00**
Catalog Number: HR2-932-**
** = reagent number A1-D6
For example, reagent number A1 = HR2-932-A1

Grid Screen Sodium Malonate - 185 ml **$138.00**
Catalog Number: HR2-947-**
** = reagent number A1-D6
For example, reagent number A1 = HR2-947-A1

Heavy Atom Au (Gold) - 100 mg **$80.00**
Catalog Number: HR2-444-**
** = reagent number 1-6
For example, reagent number 1 = HR2-444-01

Heavy Atom Hg (Mercury) - 100 mg **$80.00**
Catalog Number: HR2-446-**
** = reagent number 1-16
For example, reagent number 1 = HR2-446-01

Heavy Atom M1 - 100 mg **$80.00**
Catalog Number: HR2-448-**
** = reagent number 1-19
For example, reagent number 1 = HR2-448-01

Heavy Atom M2 - 100 mg **$80.00**
Catalog Number: HR2-450-**
** = reagent number 1-18
For example, reagent number 1 = HR2-450-01

Heavy Atom Pt (Platinum) - 100 mg **$80.00**
Catalog Number: HR2-442-**
** = reagent number 1-12
For example, reagent number 1 = HR2-442-01

Index - 185 ml **$138.00**
Catalog Number: HR2-944-**
** = reagent number 1-96
For example, reagent number 1 = HR2-944-01

MembFac - 185 ml **$138.00**
Catalog Number: HR2-920-**
** = reagent number 1-48
For example, reagent number 1 = HR2-920-01

Natrix - 185 ml **$138.00**
Catalog Number: HR2-918-**
** = reagent number 1-48
For example, reagent number 1 = HR2-918-01

PCT - 185 ml **$138.00**
Catalog Number: HR2-940-**
** = reagent number A1-B2
For example, reagent number A1 = HR2-940-A1

PEG/Ion Screen - 185 ml **$138.00**
Catalog Number: HR2-922-**
** = reagent number 1-48
For example, reagent number 1 = HR2-922-01

PEG/Ion Screen 2 - 185 ml **$138.00**
Catalog Number: HR2-998-**
** = reagent number 1-48
For example, reagent number 1 = HR2-998-01

PEGRx 1 - 185 ml **$138.00**
Catalog Number: HR2-982-**
** = reagent number 1-48
For example, reagent number 1 = HR2-982-01

PEGRx 2 - 185 ml **$138.00**

** = reagent number 1-15
For example, reagent number 1 = HR2-902-01

StockOptions Imidazole - 185 ml **$162.00**

Catalog Number: HR2-995-**
** = reagent number 1-17
For example, reagent number 1 = HR2-995-01

StockOptions MES - 185 ml **$138.00**

Catalog Number: HR2-943-**
** = reagent number 1-20
For example, reagent number 1 = HR2-943-01

StockOptions pH - 185 ml

Catalog Number: HR2-941-**

Reagents 1-39	**$139.00**
Reagents 40-45	**$151.00**

** = reagent number 1-45
For example, reagent number 1 = HR2-941-01

StockOptions Sodium Acetate - 185 ml **$150.00**

Catalog Number: HR2-933-**
** = reagent number 1-21
For example, reagent number 1 = HR2-933-01

StockOptions Sodium Cacodylate - 185 ml **$221.00**

Catalog Number: HR2-939-**
** = reagent number 1-24
For example, reagent number 1 = HR2-939-01

StockOptions Sodium Citrate - 185 ml **$173.00**

Catalog Number: HR2-935-**
** = reagent number 1-24
For example, reagent number 1 = HR2-935-01

StockOptions Sodium HEPES - 185 ml **$190.00**

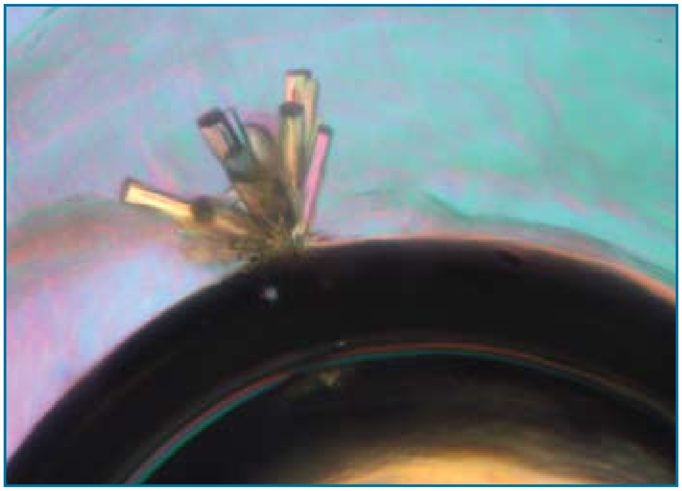
Catalog Number: HR2-931-**
** = reagent number 1-15
For example, reagent number 1 = HR2-931-01

StockOptions Tris - 185 ml **$169.00**

Catalog Number: HR2-900-**
** = reagent number 1-21
For example, reagent number 1 = HR2-900-01

StockOptions Tris Hydrochloride - 185 ml **$139.00**

Catalog Number: HR2-937-**
** = reagent number 1-21
For example, reagent number 1 = HR2-937-01



Crystals growing on a bubble.

HAMPTON
RESEARCH

APPLICATION

- Crystallization grade reagents for formulating screens or for optimization

FEATURES

- Quantitive formulation
- Lot to lot consistency
- Synergistic with Hampton Research screens & kits
- Quality and convenience
- Sterile filtered

DESCRIPTION

Optimize reagents are quantitatively formulated macromolecular crystallization grade reagents designed specifically for the crystallization of proteins, peptides, and nucleic acids. Each Optimize solution is formulated using high purity salts, polymers, and buffers. Sterile filtered Optimize reagents are formulated at convenient, ready to use concentrations. Optimize reagents remove the guesswork and make the process of reproducing preliminary screening conditions and general optimization faster, easier, and more convenient. When using Optimize reagents, a scientist moves directly from the screen to the optimization with no time wasted searching for and formulating salts, buffers, and viscous polymers. Each Optimize reagent is supplied with a Certificate of Analysis as documentation of reagent quality and performance. Optimize buffer reagents are supplied with calibrated titration curves to make titration easy, fast, and accurate.

POLYMERS

Ethylene imine polymer

HR2-599 50% solution 200 ml $78.00

$\left(-NHCH_2CH_2-\right)_x\left(-\underset{CH_2CH_2NH_2}{N}-CH_2CH_2-\right)_y$

Synonyms: PEI or Poly(ethylene imine) or
Poly(ethyleneimine) solution or Ethyleneimine polymer solution
M_r 600,000 - 1,000,000 CAS [9002-98-6] EC No 205-793-9
Density: 1.08 g/mL at 20°C Measured pH Range: 12.0 - 12.1 at 25°C
Refractive Index n20/D: 1.450 Conductivity Range: 244.3 - 257.0 µS at 25°C

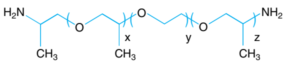
Jeffamine® ED-2001 pH 7.0

HR2-597 50% w/v solution pH 7.0 200 ml $98.00

Synonyms: O,O'-Bis(2-aminopropyl) polypropylene glycol-block-polyethylene glycol-block-polypropylene glycol 1,900 $CH_3CH(NH_2)CH_2(OCH_2CH_2)_nOCH_2CH(NH_2)CH_3$
M_r ~2,000 CAS [65605-36-9]
Refractive Index Range: 1.40637 - 1.40666 at 20°C
Conductivity Range: 4.0 - 5.7 mS at 25°C
pH before titration with Hydrochloric acid is > 10
Final measured pH of HR2-597 is 7.0

$H_2N\underset{CH_3}{C}HCH_2-(O\underset{CH_3}{C}HCH_2)_a-(OCH_2CH_2)_b-(OCH_2\underset{CH_3}{C}H)_c-NH_2$

$b \approx 38.7, (a+c) \approx 6.0$



$y \approx 39, (x+z) \approx 6$

Jeffamine® M-600®

HR2-501 50% v/v solution pH 7.0 200 ml $94.00
HR2-503 100% solution (untitrated pH >12) 200 ml $94.00

Synonyms: O-(2-Aminopropyl)-O'-(2-methoxyethyl)polypropylene glycol 500 or Polypropylene glycol 500 mono-2-aminoethyl mono-2-methoxyethyl ether $CH_3OCH_2CH_2O[CH(CH_3)CH_2O]_nCH_2CH(NH_2)$
M_r 600 CAS [77110-54-4] Density: 0.983 g/mL at 20°C

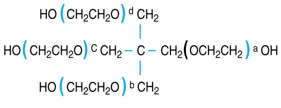
HR2-501: Refractive Index Range: 1.40754 - 1.40988 at 20°C
Conductivity Range: 8.8 - 10.3 mS at 25°C

HR2-503: Refractive Index Range: 1.44501 - 1.44546 at 20°C
Conductivity Range: 0.0 - 0.1 µS at 25°C

Pentaerythritol ethoxylate (3/4 EO/OH)

HR2-743 40% v/v solution 200 ml $46.00

Synonyms: Pentaerythritol ethoxylate (15/4 EO/OH)
$C(CH_2(OCH_2CH_2)_nOH)_2$ Average M_n ~270
CAS [30599-15-6] EC No 500-071-2
Density: 1.2 g/mL at 25°C (lit.)
Measured pH Range: 7.5 - 8.7 at 25°C
Refractive Index: 1.39719 at 20°C
Conductivity Range: 37.8 - 40.5 µS at 25°C

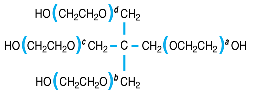


a + b + c + d ~ 3

Pentaerythritol ethoxylate (15/4 EO/OH)

HR2-745 50% v/v solution 200 ml $54.00

Synonyms: Pentaerythritol ethoxylate (3/4 EO/OH)
$C(CH_2(OCH_2CH_2)_nOH)_4$, N ~3.75 Average M_n ~797
CAS [30599-15-6] EC No 500-071-2
Density: 1.2 g/mL at 25°C (lit.)
Measured pH Range: 5.2 - 6.0 at 25°C
Refractive Index Range: 1.41401 - 1.41578 at 20°C
Conductivity Range: 4.2 - 11.4 µS at 25°C

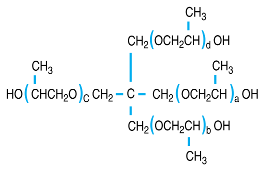


a + b + c + d ~ 15

Pentaerythritol propoxylate (5/4 PO/OH)

HR2-739 50% v/v solution 200 ml $54.00

Synonyms: Pentaerythritol propoxylate
$C[CH_2[OCH_2CH(CH_3)]_nOH]_4$, N ~5 Average M_n ~426
CAS [9051-49-4] EC No 500-030-9
Density of 100% solution: 1.05 g/mL at 25°C
Measured pH Range: 7.7 - 8.3 at 25°C
Refractive Index: 1.40424 - 1.40433 at 20°C
Conductivity Range: 3.8 - 4.7 µS at 25°C

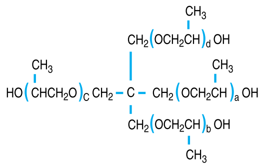


a + b + c + d ~ 5

Pentaerythritol propoxylate (17/8 PO/OH)

HR2-741 50% v/v solution 200 ml $58.00

Synonyms: Pentaerythritol propoxylate
$C(CH_2(OCH_2CH(CH_3))_nOH)_4$, N = 2.1 Average M_n ~629
CAS [9051-49-4] EC No 500-030-9
Density: 1.05 g/mL at 25°C (lit.)
Measured pH Range: 4.3 - 4.6 at 25°C
Refractive Index: 1.40418 at 20°C
Conductivity Range: 6.1 - 6.9 µS at 25°C

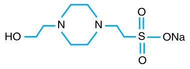


a + b + c + d ~ 5

Poly(acrylic acid sodium salt) 5,100

HR2-773 50% w/v solution 200 ml $95.00

Synonyms: Poly(sodium acrylate) or Sodium polyacrylate
$C_3H_3NaO_2$ M_r 94.04 CAS [9003-04-7]
Measured pH Range: 6.4 - 6.9 at 25°C

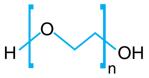


Refractive Index Range: 1.40716 - 1.40821 at 20°C Conductivity Range: 30.5 - 41.1 mS at 25°C

Polyethylene glycol 200

HR2-601 100% solution 200 ml $30.00

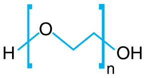
Synonyms: PEG 200 $H(OCH_2CH_2)_nOH$ M_r 190 - 210
CAS [25322-68-3] EC No 500-038-2
Density: 1.124 g/mL at 20°C
Measured pH Range: 8.0 - 10.2 at 25°C



Refractive Index Range: 1.46008 - 1.46083 at 20°C Conductivity Range: 2.5 - 2.8 µS at 25°C

Polyethylene glycol 300

HR2-517	**100% solution**	**200 ml**	**$45.00**



Synonyms: PEG 300 $H(OCH_2CH_2)_nOH$ M_r 285 - 315
CAS [25322-68-3] EC No 500-038-2 Density: 1.125 g/mL at 20°C
Measured pH Range: 8.0 - 8.5 at 25°C
Refractive Index Range: 1.46492 - 1.46535 at 20°C
Conductivity Range: 7.7 - 8.1 µS at 25°C

Sodium potassium phosphate (Quik Optimize)

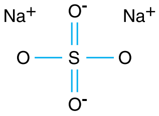
HR2-223 Quik Optimize 100 ml, 2 bottles $175.00

Quik Optimize kit includes:
4.0 M Sodium phosphate monobasic monohydrate, 100 ml (HR2-551)
M_r 137.99 $NaH_2PO_4 \cdot H_2O$ CAS [10049-21-5] EC No 231-449-2
4.0 M Potassium phosphate dibasic, 100 ml (HR2-635)
M_r 174.18 K_2HPO_4 CAS [7758-11-4] EC No 231-834-5

Each kit contains a dilution table to create any pH (between 5.0 and 8.2) and any concentration (between 0.2 and 4.0 M) in 0.2 increments. This kit can be used to reproduce Quik Screen (HR2-221) reagent conditions as well as formulate optimization conditions.

Sodium sulfate decahydrate

HR2-673 1.0 M solution 200 ml $75.00



Synonyms: Glauber's salt
$Na_2SO_4 \cdot 10H_2O$ M_r 322.20 CAS [7727-73-3]
EC No 231-820-9 Purity $\geq$ 99.0%
Measured pH Range: 6.0 - 7.8 at 25°C
Refractive Index Range: 1.35184 - 1.35190 at 20°C
Conductivity Range: 89.0 - 96.1 mS at 25°C

Ca	≤ 0.002%	Fe	≤ 0.0005%	N	≤ 0.0005%

Citric acid BIS-TRIS propane Buffer (Useful pH Range: 2.5 - 9.5)

HR2-831	**1.0 M Citric acid**	**100 ml**	**$33.00**
HR2-833	**1.0 M BIS-TRIS propane**	**100 ml**	**$119.00**

Citrate BIS-TRIS propane (CBTP) is a buffer system useful across pH 2.5 to 9.5. Using CBTP one can use a single buffer system to screen pH 2.5 to 9.5 by varying the ratio of Citric acid to BIS-TRIS propane. Although the two buffer reagents are made available separately for convenient, individual replacement, they are designed to be used together, with the supplied CBTP buffer titration table to create a crystallization buffer system covering pH 2.5 to 9.5.
HR2-831: Measured pH Range: 1.2 - 1.5 at 25°C
Refractive Index: 1.35682 at 20°C Conductivity Range: 7.8 - 8.7 mS at 25°C
HR2-833: Measured pH Range: 11.2 - 11.3 at 25°C
Refractive Index: 1.38076 at 20°C Conductivity Range: 309.0 - 364.0 µS at 25°C

WHAT ARE NDSBS?

DESCRIPTION

Non Detergent Sulfobetaines (NDSB) are a new family of non denaturing protein solubilizing agents with a wide range of applications. NDSBs have been used for protein extraction, solubilization, and crystallization. NDSBs are zwitterionic, they can be removed by dialysis since they do not form micelles, and they do not alter the biophysical properties of biological buffers.

This particular class of reagent was developed by Laurent Vuillard (University of Cambridge, Department of Pathology, UK) in collaboration with T. Rabilloud (CENG, Grenoble, France).

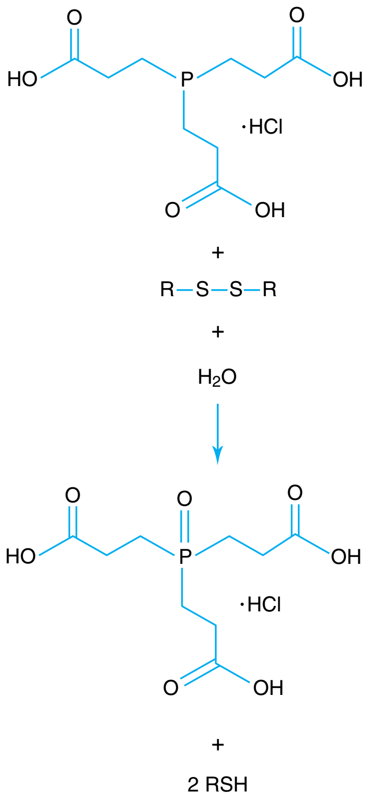
TCEP HYDROCHLORIDE

APPLICATION

- Stable reducing agent for crystallization trials

FEATURES

- Highly soluble
- Odorless and non-volatile
- Effective at acidic and alkaline pH



DESCRIPTION

Try using TCEP hydrochloride instead of dithiothreitol (DTT) as a reducing agent in your crystallization setups. TCEP hydrochloride is soluble in water to 310 g per L. TCEP hydrochloride is Tris (2-carboxyethyl)phosphine hydrochloride. It is an odorless (non-volatile) reducing agent that is more stable and effective than DTT or 2-Mercaptoethanol. Unlike DTT, TCEP hydrochloride retains its reducing power at acid pHs (pH 5) and at pHs above 7.5. It is unreactive toward other functional groups found in proteins. Unlike DTT (dithiothreitol), TCEP hydrochloride does not contain a free thiol, and therefore does not require removal before reaction with a thiol-reactive reagents. It reduces disulfides but apparently not mercury–thiol bonds. TCEP hydrochloride is compatible with many heavy atoms and may be used during heavy atom derivatization. It is more stable at a higher pH and at higher temperatures than is DTT and for a longer period of time in buffers without metal chelators such as EGTA.

PERFLUOROPOLYETHER PFO-X175/08

APPLICATION

- Cryoprotectant

FEATURES

- Perfluoropolyether oil
- Low viscosity
- Low surface tension

DESCRIPTION

Used during cryocrystallography to displace and reduce the amount of water (mother liquor, reagent) on the crystal after the crystal is mounted in a cryoloop. Coating the crystal with oil can minimize evaporation from the crystal and reduce exposure and slow diffusion of air (oxygen) to the crystal.

PARATONE-N

APPLICATION

- Cryoprotectant

DESCRIPTION

Paratone-N is a viscous cryoprotectant for both small and large molecule crystallography.[1] Mildly air-unstable, small molecule compounds can be coated with Paratone-N under an inert atmosphere. The Paratone-N protected crystal sample can be cryocooled in a chilled nitrogen gas stream. Paratone-N has also been used successfully as a cryoprotectant for biological macromolecule crystals. It is used during cryocrystallography to displace and reduce the amount of water (mother liquor, reagent) on the crystal after the crystal is mounted in a cryoloop. Coating the crystal with Paratone-N can minimize evaporation from the crystal and reduce exposure and slow diffusion of air (oxygen) to the crystal.

Paratone-N is also known as Parabar 10312, Paratone 8277, and Infineum V8512.

FLUORINERT™ FC-70 FLUID

APPLICATION

- Drop floating crystallization

FEATURES

- Viscosity similar to water with approximately 75% greater density
- Stable
- Completely fluorinated

figure 1
Floating drop vapor diffusion technique

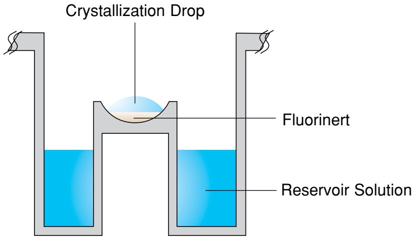

figure 2
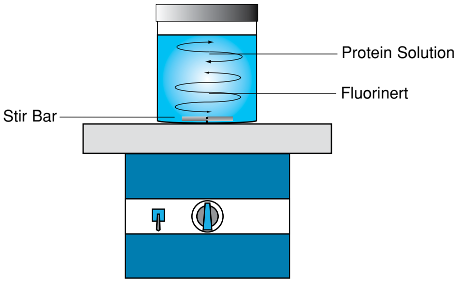
Floating and stirring technique



DESCRIPTION

Floating Drop Vapor Diffusion

The floating drop vapor diffusion technique[1] has been described using Fluorinert FC-70. The transparent and high density FC-70 liquid is not miscible with most crystallization reagents, samples, oil, or water. When Fluorinert liquid and the sample/reagent are mixed, the sample/reagent drop immediately separates from the Fluorinert and floats on top of the Fluorinert (see figure 1). Crystals grown using the floating drop technique do not stick to the crystallization plate. As the sample/reagent/crystal is not miscible with the Fluorinert liquid, complete separation of the crystal from the Fluorinert is straight forward. Crystals grown using the floating drop technique can be removed from the drop without mechanical damage. Drop volumes can vary widely using the floating drop method. Handling of the crystal is improved.

Floating and Stirring Technique (FAST)

The floating and stirring technique (FAST)[2] has been described using Fluorinert FC-70 liquid. The method, which involves a sample and reagent mixture applied over a non-miscible dense liquid (Fluorinert FC-70) without contact and slow stirring can also be combined with slow cooling or warming (See figure 2). The floating and stirring method has been reported to accelerate growth of the crystal as well as prevent subsequent spontaneous nucleation. The method has been used with seed crystals to promote the growth of a larger crystal without the appearance of subsequent crystals.

Fluorinert: FC-70 Fluid
Mr: 820
CAS number: [86508-42-1]
Pour point: -25°C
Boiling point: 215°C
Nonflammable
Vapor pressure: 15 pascals
Liquid density: 1,940 kg/m3
Kinematic viscosity: 12 centistokes
Absolute viscosity: 24 centipoise
Coeffecient of expansion: 0.0010°C-1
Surface tension: 18 dynes/cm
Refractive index: 1.303
Water solubility: 8 ppmw
Ozone depletion potential: 0
Dielectric strength: 40 kV, 0.1” gap
Dielectric constant: 1.98
Electrical resistivity: 2.3 x 1015 ohm cm
Appearance: Clear, colorless

MICROBATCH CRYSTALLIZATION OILS

APPLICATION

- Microbatch crystallization

FEATURES

- Screen different temperatures without condensation
- Protect the sample from oxidation
- Under oil crystallization

DESCRIPTION

Oils used for microbatch and modified microbatch crystallization under oil.

Al's Oil is a 50:50 (volume:volume) mixture of Paraffin Oil and Silicon Oil.

Paraffin oil
Synonym: Mineral oil
CAS Number [8042-47-5]
EC Number 2324558
RTECS PY8047000
Appearance Colorless, clear, viscous liquid
Refractive Index n20/D 1.467 (literature) n20/D 1.468
IR Spectroscopy Grade
Density 0.85 g/ml at 20°C
Viscosity 40-42 CST at 25°C

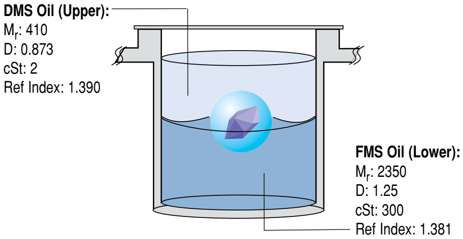
CONTAINERLESS CRYSTALLIZATION

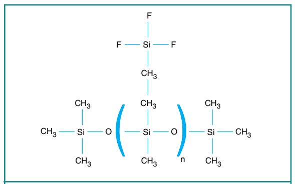
APPLICATION

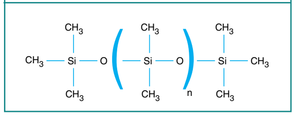
- Contact free crystallization by microbatch under oil

FEATURES

- Utilizes two immiscible oils to create a simulated containerless system







DESCRIPTION

Containerless crystallization is a micromethod of batch crystallization of proteins under conditions where the sample and precipitant have no contact with the surface of the crystallization plate. Drops (2 to 20 μl) of sample combined with crystallization reagent are pipetted at the interface between two layers of inert and immiscible silicon oils contained in a 24, 48, or 96 well plate and sealed. Plates and plain cover slides are available separately. It is easier to position drops into the center of the oil using plates with larger reservoirs (i.e. 24 and 48 well plates) but this requires more oil. When using the 96 well plates, drops of higher density (polymer based reagents such as PEG) tend to migrate to the side walls of the plate.

The method relies upon the use of two immiscible oils (FMS and DMS). Poly-3, 3, 3-Trifluoropropylmethylsiloxane (FMS), a branched silicone compound, has a higher density than Polydimethylsiloxane (DMS). Therefore, one can create a bilayer with a distinct interface by placing the two oils in a reservoir. Neither DMS nor FMS is miscible with water. The oils are compatible with most crystallization reagents including but not limited to buffers, salts, polymers, and MPD. Additional protein or crystallization reagents can be added to the drop in the oil. Crystal mounting as well as seeding can be performed while the drop is in the oil. During crystal mounting, the drop will maintain a spherical shape and decrease in size as sample is withdrawn. During seeding, crystal seeds will sediment to the bottom of the drop. It has been observed that large, perfect, single crystals can be grown using the containerless crystallization method. Crystals typically nucleate at the oil/water interface and grow into the drop.

OPTIMIZE™ - SILICA HYDROGEL KIT

APPLICATION

- Quick & easy kit format for crystallization in gels

FEATURES

- Proprietary Silica Hydrogel formulation with neutral pH
- Gel matrix can reduce nucleation & sedimentation

DESCRIPTION

Gels are a very efficient media for growing macromolecular crystals.[1-5] Silica gels in particular have the advantage in that they are stable, usable over a wide range of temperatures (0-60°C), and are compatible with a wide variety of precipitants and additives used for crystal growth.

Gels can reduce nucleation and sedimentation, provide added stability, and allow crystals to grow larger. The porous network minimizes natural convection. Crystals are suspended in the gel network so that they do not form sediments and can grow free from strain exerted by the container or other crystals. Heterogeneous and secondary nucleation are reduced in the presence of a Silica Hydrogel.[3] The Silica Hydrogel can be used for liquid-gel, liquid-gel-liquid, vapor diffusion, as well as dialysis crystallization methodologies. The gel is compatible with a wide range of salts, polymers, organic solvents, and buffers used for macromolecular crystallization in a pH range from 3 to 10.

Each Silica Hydrogel kit contains 12 tubes of Sodium silicate solution and 12 tubes of Acetic acid solution, 500 μl each. All solutions are sterile filtered and formulated using ultra-pure water. Crystallization accessories are sold separately.

OPTIMIZE™ - LM AGAROSE

APPLICATION

- Crystallization in agarose gel

FEATURES

- Gel matrix can reduce nucleation and sedimentation
- Crystallization grade
- Low melting agarose

DESCRIPTION

Low melting (LM) agaroses are the result of a derivatization process by organic synthesis. The main properties of these agaroses are their low melting and gelling temperatures when compared with standard agaroses. LM agaroses have higher clarity (gel transparency) than gels of standard agaroses. The gelling temperature of LM agaroses is 24 to 28°C.

The structure of the polysaccharide is that of a galactan, formed by linking agarobioses by links 1-3, 1-4. This chemical structure gives agaroses the capacity to form strong gels even at low temperatures. The gels have a macroreticular structure with a very open mesh which can be adjusted simply by varying the concentration of the agarose. The macroreticule structure of the agarose gel is formed by hydrogen bonds, which makes the gel reversible, transforming the gel into a solution by heating. The absence of ionic groups makes the gel a neutral structure. With no interaction, macromolecules can migrate through the gel mesh, making the gel an efficient sieve for biological macromolecules.

OPTIMIZE™ - IZIT CRYSTAL DYE™

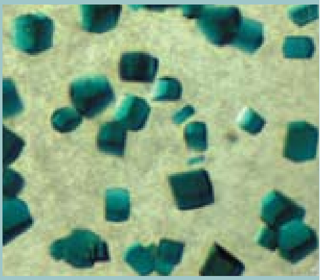
APPLICATION

- Differentiate protein crystals from salt crystals

FEATURES

- 0.22 micron sterile filtered solution
- Small molecule dye penetrates solvent channels of macromolecular crystals, coloring the crystals blue.
- Salt crystals cannot absorb Izit and remain colorless

DESCRIPTION



A crystal! Is it protein or is it salt? Have you ever asked yourself this question? Sure you could mount the crystal in question and take a quick look at the diffraction pattern but perhaps you're too lazy or you don't have an x-ray facility. Well, there's always the crush test. One simply takes a MicroTool™ or Crystal Probe™ and crushes the suspect crystal. A click or solid crunch is indicative of salt while a powder or silent destruction might indicate one just destroyed a perfectly good protein crystal. Izit is here to help. Simply place one μl of Izit in the sample drop and wait for an hour or so. Izit is a small molecule dye which will fill the solvent channels in protein crystals, coloring the crystals blue. With the appropriate dilution, Izit will in fact leave a clear drop with blue crystals, as illustrated in the picture to the right. Salt crystals do not possess these large solvent channels. Therefore, Izit cannot enter the crystal, leaving one with a clear crystal and a blue drop. Izit is especially nice for small microcrystals or questionable precipitate. The 0.5 ml vial of Izit is sufficient for more than thousands of crystallization drops.

Each Izit vial contains 0.5 ml of Izit dye. All solutions are formulated using ultra-pure water and are sterile filtered. Crystallization accessories are sold separately.

DESCRIPTION

StockOptions reagent kits are reagent tool boxes for the macromolecular crystal grower. They offer precisely formulated, high quality crystallization grade reagent stocks in convenient, cost-effective kits. The chemicals utilized in these kits are the same crystallization grade, ultra-high purity chemicals utilized in the Hampton Research kits such as Crystal Screen™ and Crystal Screen 2™. StockOptions reagents are carefully formulated under strict quality standards to ensure reliable performance and lot-to-lot consistency.

Each reagent in a StockOptions kit is available in convenient concentration, making crystal setups quick and easy. Gone is the tedious task of finding and sourcing reagents, as well as costly and time-consuming reagent formulation.

Preformulated reagents also reduce the activation energy between the discovery of preliminary screen conditions and the task of setting experiments for optimization. The generation of custom screens or optimized conditions now simply involves pipetting StockOptions reagents from convenient kits.

StockOptions Salt contains 49 unique salts, preformulated at convenient stock concentrations, each in 10 ml volumes, all in a single kit with a 5" x 9" footprint that saves precious lab space. It is designed to help researchers improve the speed, accuracy, precision, and quality of the formulation of crystallization optimization solutions. Researchers can use the individual StockOptions reagents to formulate custom screen solutions or accurately reproduce standard screen solutions from Hampton Research crystallization kits. All one needs to do is select the reagent and pipet.

The convenience also reduces the chance of errors. Preformulated stocks remove calculation, measurement, and formulation errors. No more second guessing how the reagent was formulated, what specific chemical was used, when it was made, or how to precisely reproduce that reagent when it is gone and more reagent is required for additional setups.

StockOptions are cost-effective, time saving reagents. When a StockOptions kit is purchased, one is using reagents as preformulated stocks in reasonable volumes. You buy only the reagents you need, not a large container of raw material that may sit out on shelves for years to come. Waste is further reduced since there is no chance for formulation or measuring errors. When you need larger volumes, Hampton Research offers individual, preformulated, sterile filtered Optimize crystallization reagents which include salts, polymers, organics solvents, and buffers. Each of the 49 salts offered in StockOptions Salt is available individually as an Optimize™ crystallization grade reagent. Optimize, Custom Shop, StockOptions, and all Hampton Research kits are synergistic research tools.

StockOptions kits also lower the costs associated with making crystallization reagents since there is no need to purchase sterile filters, filtration devices, or pre-sterilized storage containers. Cost savings are also extended to labor since time can now be better utilized for sample production and purification or setting crystallization experiments.

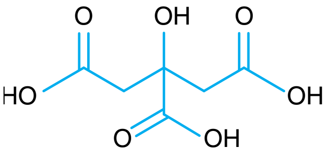
Preformulated stocks remove calculation, measurement, and formulation errors. No more second guessing how the reagent was formulated, what specific chemical was used, when it was made, or how to precisely reproduce that reagent when it is gone and more reagent is required for additional setups.

STOCKOPTIONS™ CITRIC ACID



pH 2.2 - 6.5

StockOptions Citric Acid buffer kit is a preformulated, sterile filtered set of titrated buffer stocks. The reagents are supplied as 1.0 M stock solutions in 10 ml volumes. Each StockOptions Citric Acid buffer reagent is carefully titrated using Sodium hydroxide. StockOptions Citric Acid is comprised of 44 unique reagents covering the pH range of 2.2 to 6.5 in 0.1 pH unit increments.

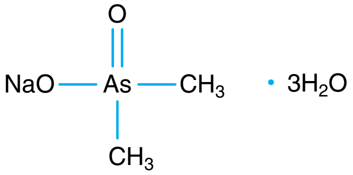
STOCKOPTIONS™ SODIUM CACODYLATE BUFFER



$(CH_3)_2As(O)ONa \cdot 3H_2O$

pH 5.1 - 7.4

StockOptions Sodium Cacodylate buffer kit is a preformulated, sterile filtered set of titrated buffer stocks. The reagents are supplied as 1.0 M stock solutions in 10 ml volumes. Each StockOptions Sodium Cacodylate buffer reagent is carefully titrated using Hydrochloric acid. The kit is comprised of 24 unique reagents covering the pH range of 5.1 to 7.4 in 0.1 pH unit increments.

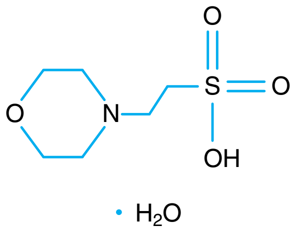
STOCKOPTIONS™ MES BUFFER



pH 5.2 - 7.1

StockOptions MES buffer kit is a preformulated, sterile filtered set of titrated buffer stocks. The reagents are supplied as 1.0 M stock solutions in 10 ml volumes. Each StockOptions MES buffer reagent is carefully titrated using Sodium hydroxide. The kit is comprised of 20 unique reagents covering the pH range of 5.2 to 7.1 in 0.1 pH unit increments.

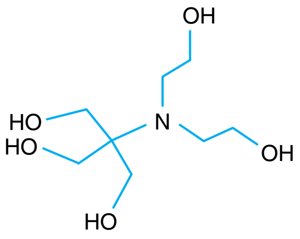
STOCKOPTIONS™ BIS-TRIS



pH 5.5 - 7.5

StockOptions Bis-Tris buffer kit is a preformulated, sterile filtered set of titrated buffer stocks. The reagents are supplied as 1.0 M stock solutions in 10 ml volumes. Each StockOptions Bis-Tris buffer reagent is carefully titrated using Hydrochloric acid. The kid is comprised of 21 unique reagents covering the pH range of 5.5 to 7.5 in 0.1 pH unit increments.

CRYOPRO™

APPLICATION

- Cryoprotectant reagent kit

FEATURES

- 36 unique cryoprotectants
- Includes cryoprotectant tutorial
- Preformulated, ready-to-use
- Polyols, organics, oils, polymers, sugars, & salts

FORMULATIONS

Reagent Number	Cryoprotectant
1	100% Glycerol
2	100% Ethylene glycol
3	100% Polyethylene glycol 200
4	100% Polyethylene glycol 400
5	80% v/v Polyethylene glycol 600
6	60% w/v Polyethylene glycol 4,000
7	50% w/v Polyvinylpyrrolidone K 15
8	100% (+/-)-2-Methyl-2,4-pentanediol
9	6.0 M 1,6-Hexanediol
10	100% 1,2-Propanediol
11	100% Paratone-N
12	100% Paraffin Oil
13	100% NVH Oil
14	100% Dimethyl sulfoxide (DMSO)
15	100% 2-Propanol
16	100% Ethanol
17	100% Methanol
18	70% w/v D-(+)-Sucrose
19	35% w/v meso-Erythritol
20	70% w/v Xylitol
21	15% w/v myo-Inositol
22	20% w/v D-(+)-Raffinose pentahydrate
23	50% w/v D-(+)-Trehalose dihydrate
24	70% w/v D-(+)-Glucose monohydrate
25	100% 2,3-Butanediol
26	100% L-(+)-2,3-Butanediol
27	5.0 M Lithium acetate dihydrate
28	10.0 M Lithium chloride
29	4.0 M Lithium formate monohydrate
30	8.0 M Lithium nitrate
31	2.0 M Lithium sulfate monohydrate
32	3.4 M Sodium malonate pH 7.0
33	3.5 M Magnesium acetate tetrahydrate
34	5.0 M Sodium chloride
35	7.0 M Sodium formate
36	7.0 M Sodium nitrate

DESCRIPTION

As in selecting reagents for crystallization, the selection of a suitable cryoprotectant involves some trial and error as well as a screening.[1-15] A suitable cryoprotectant, when mixed with the crystal and crystallization reagent, will cool to cryogenic temperature without ice formation and damage to the crystal. To assay for the proper concentration of cryoprotectant in the reagent used to grow the crystal, one can mix the cryoprotectant with the crystallization reagent and employ the desired cooling method. For example, place the solution in a CryoLoop™ and place the CryoLoop in a cryostream. Observe for ice formation either visually or with x-ray diffraction. Upon cooling, a transparent drop and x-ray diffraction pattern, free of powder diffraction rings or "ice rings" indicates success. The appearance of a cloudy drop or "ice rings", indicates an inappropriate cryoprotectant concentration or cryoprotectant. Incrementally increase the concentration and/or composition of the cryoprotectant serially 5 to 10% and repeat until the cooled drop remains clear while in the cryostream. Once a clear drop is achieved in the cryostream, this is typically a good starting point for cryopreservation of the crystal.

Some crystals can simply be dipped or washed quickly in a simple cryoprotectant such as 30% glycerol for successful cryopreservation. However, when all else fails, a rational assay of each cryoprotectant with incremental increases in cryoprotectant concentration, as well as a test of mixtures (i.e. a mixture of sugars or a sugar mixed with Ethylene glycol) may be required to determine the best cryoprotectant for a crystal.

Each CryoPro - Cryoprotectant kit contains 36 unique cryoprotectants including organics, oils, polyols, salts, sugars, and polymers. 35 of the 36 reagents are supplied in 10 ml volumes. A single reagent L-(+)-2,3-Butanol is supplied in a 0.2 ml aliquot. CryoPro is convenient and cost-effective.

Ready-to-use cryoprotectants are sterile filtered and formulated with ultra-pure water, using high purity reagents. Many of the individual cryoprotectants are available as a 100 ml or 200 ml Optimize™ reagent. Please refer to the CryoPro Formulations pdf file to find the catalog number for the equivalent Optimize.

CRYSCHEM™ PLATE

APPLICATIONS

- Sitting drop crystallization
- Heavy atom soaks
- Seeding

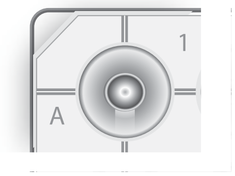
FEATURES

- Optically clear, concave sitting drop post
- Smooth, flat top for easy seal

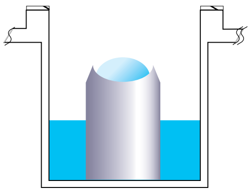
MATERIAL

- Optically clear polystyrene

Top



Side



DESCRIPTION

The Cryschem Plate is a 24 well sitting drop plate that is sealed with clear sealing tape. The plate is supplied with a raised cover so the plate can also be sealed with vacuum grease and plain glass or plastic cover slides (22 mm diameter). The stackable, 24 well plates have distortion-free, flat bottom wells and a concave sitting drop post in the center of the well for concentric equilibration of the drop with the reagent. Each plate is individually sealed. The top of the plate and each of the 24 wells is a single, flat plane for smooth and easy seal application. Well spacing provides for a large seal area between wells to prevent cross contamination and evaporation. Approximate size: 15.1 cm x 10.6 cm x 2.2 cm. Approximate well size: 1.6 cm x 1.5 cm. Typical fill volume: 500 to 1,000 μl. Well capacity: 1.5 ml. Maximum drop volume on post: 40 μl. Recommended seal: HR3-511 Crystal Clear Sealing Tape (1.88 inch x 43.7 yard roll, with cutter) or HR4-511 Crystal Clear Sealing Tape (1.88 inch x 60 yard roll, without cutter).

The Cryschem 24-1 SBS Plate is a smaller, SBS footprint 24 well sitting drop microplate that is sealed with tape or film. The plate is supplied with a raised cover so the plate can also be sealed with vacuum grease and plain glass or plastic cover slides (18 mm diameter). The stackable, 24 well plates have distortion-free, flat bottom wells and a concave sitting drop post in the center of the well for concentric equilibration of the drop with the reagent. Each plate is individually sealed. The top of the plate and each of the 24 wells is a single, flat plane for smooth and easy seal application. Well spacing provides for a large seal area between wells to prevent cross contamination and evaporation. Approximate size: 127.8 mm x 85.5 mm x 14.4 mm. Typical fill volume: 500 to 700 μl. Maximum drop volume on post: 12 μl. Recommended seal: HR3-609 Crystal Clear Sealing Film (100 pack), HR4-521 ClearSeal Film (100 pack) or HR4-506 Crystal Clear Sealing Tape (3 inch x 55 yard roll).

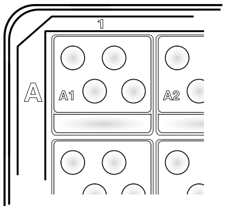
INTELLI-PLATE™ 24-4 WELL

APPLICATION

- Sitting drop crystallization

FEATURES

- 4 drop wells per reservoir
- Optically clear polystyrene
- Alphanumeric labeled drop wells visible under microscope



Intelli-Plate™ 24-4 well

DESCRIPTION

The Intelli-Plate 24-4 is a 24 well sitting drop plate for crystallization screening and optimization. It features 4 reagent wells along the y-axis (A-D) and 6 reagent wells along the x-axis (1-6). The reagent reservoir is typically filled with 250 μl and is capable of holding between 200 and 650 μl. The 4 drop wells are arranged at the top of each well and can hold up to 8 μl (5 μl for hydrophobic reagents such as MPD).

The Hampton Research ClearSeal Film™ and Sealing Film Applicator are used to seal the Intelli-Plate when a sitting drop experiment is performed. The advanced film is a transparent, polyolefin film with clear, pressure-sensitive, silicone adhesive. The film is pre-cut to perfectly fit 96 well crystallization plates and is complete with 1 cm wide, perforated end tabs which makes handling and positioning of the film easy, without fear of fingerprints getting into the view field. The Sealing Film Applicator is a small, hand-held applicator which should be used to create a consistent film seal across the entire crystallization plate. The Intelli-Plate can also be sealed using one of the clear sealing tapes supplied in a roll format.

The height of all Intelli-Plate 24-4 is 0.560 inches. The Art Robbins Instruments catalog number for this plate is 102-0004-00.

24 WELL CRYSTALLIZATION PLATES

VDX™ PLATE

APPLICATIONS

- Hanging drop crystallization
- Sitting drop crystallization with Micro-Bridges® or Glass Sitting Drop Rods™
- Dialysis crystallization with Dialysis Buttons™

FEATURES

- Compatible with 22 mm diameter square and circle cover slides
- 24 well plate with raised cover
- Extremely versatile and cost-effective crystallization platform
- Optically clear plastic

DESCRIPTION

24 well crystallization plate for hanging drop or sitting drop vapor diffusion crystallization (when used with Micro-Bridges or Glass Rods), or Dialysis crystallization (when used with Dialysis Buttons). Stackable, optically clear plastic 24 well plates with raised covers (to allow room for cover slides) and flat bottoms for exceptional optics. Raised, wide rings around each reservoir (well) minimize cross contamination and allow each well to be individually sealed with 22 mm diameter circle or square cover slides. Plates are individually wrapped and supplied without sealant. 15.0 cm x 10.8 cm plate footprint is convenient for manual pipetting and well access while at the same time compatible with some automated liquid handling systems. Approximate dimensions: 15.0 cm x 10.6 cm x 2.2 cm. Approximate well size: 1.7 cm x 1.6 cm. Typical well volume: 500 to 1,000 μl. Well capacity: 3.5 ml.

VDXm™ PLATE

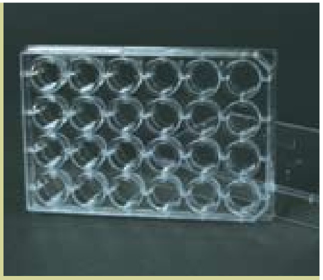
APPLICATION

- Hanging drop crystallization

FEATURES

- 24 well plate with raised cover
- Compatible with 18 mm diameter circle cover slides
- Optically clear plastic
- 128 mm x 85 mm microplate footprint

DESCRIPTION



24 well plate for hanging drop vapor diffusion crystallization with a microplate footprint. Stackable, optically clear plastic, 24 well plates with raised covers (to allow room for cover slides) and flat bottoms for exceptional optics. Raised, wide rings around each reservoir (well) minimize cross contamination and allow each well to be individually sealed with 18 mm diameter circle cover slides. Plates are individually wrapped and supplied without sealant. The microplate footprint is space-saving and compatible with automated liquid handling systems. Approximate dimensions: 128 mm x 85 mm. Approximate well ID: 14.4 mm. Typical well volume: 100 to 500 μl.

- Sitting drop when used with CrystalBridge
- ComboPlate has flat, raised rings about each well to minimize spills and cross contamination
- ComboPlate seals with 18 mm glass or plastic cover slides
- Slightly raised protection lid

MATERIALS

- Polystyrene

DESCRIPTION

The Greiner ComboPlate is a 24 well plate with a raised cover in an SBS microplate footprint. The plate, supplied without sealant, can be sealed with an 18 mm diameter cover slide and sealant for hanging drop crystallization. When used with the Greiner CrystalBridge, the ComboPlate can be used for sitting drop crystallization and sealed with sealing film/tape or 18 mm diameter cover slide and sealant. Dimensions: 127.76 mm x 85.48 mm x 18.8 mm. Well depth: 16.28 mm. 3.3 ml well capacity. Typical fill volume: 0.5 - 1.0 ml. Supplied with cover. The Greiner CrystalBridge is a polystyrene sitting drop pedestal with a concave drop well (45 μl capacity) and is designed specifically for the ComboPlate.

LINBRO® PLATE

APPLICATIONS

- Hanging drop crystallization
- Sitting drop crystallization with Micro-Bridges® or Glass Sitting Drop Rods™
- Dialysis crystallization with Dialysis Buttons™

FEATURES

- 24 well plate with cover
- Compatible with 22 mm diameter circle and square cover slides
- Optically clear plastic

DESCRIPTION

The Linbro 24 well plate with cover is made of clear, rigid, polystyrene and used primarily for hanging drop vapor diffusion crystallization. Sitting drop vapor diffusion may be performed when used with Micro-Bridges or Glass Sitting Drop Rods. Plates supplied without sealant. Compatible with 22 mm diameter circle and square cover slides. Each plate is individually wrapped and sterile. Wide, raised rings around each reservoir minimizes cross contamination and allows each individual well to be sealed using vacuum grease, DC 7 Release Compound or immersion oil and a siliconized or plain cover slide. Cover is not raised but can be raised by placing wax or mounting clay in each of the four corners of the cover. The stackable plates have distortion-free, flat-bottom wells of fine clarity. Wells are identified by lettered rows A through D and numbered columns 1 through 6. Approximate dimensions: 15.0 cm x 10.8 cm x 2.2 cm. Approximate well size: 1.7 cm x 1.6 cm. Typical well volume: 700 to 1,000 μl. Individual well capacity: 3.5 ml

VDX™ PLATE (MODULAR)

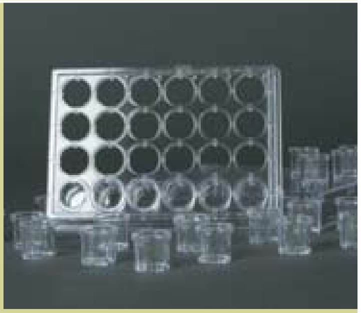
APPLICATIONS

- Sitting, hanging drop, and dialysis crystallization
- Modular wells for temperature studies[1]

FEATURES

- Removable wells
- 24 well plate with raised cover
- Wells available with or without sealant
- Use with 22 mm diameter circle and square cover slides
- Optically clear plastic

DESCRIPTION



The Modular VDX Plate is a standard 24 well VDX Plate™ with individually removable wells. The modular format, consisting of a VDX frame and removable wells creates a very flexible plate format for screening and optimization of crystallization experiments.

Preliminary crystallization screens can be set in the Modular VDX Plate. Once the results are scored, the wells can be removed and organized into separate frames for optimization and observation. Preliminary crystallization screens typically evaluate a diverse array of reagents, reagent concentrations, pH values, and other variables that can influence sample solubility and crystallization. These crystallization variables, combined in a single well can have a unique effect on the sample solubility and are useful for screening preliminary crystallization conditions. The crystallization screen typically delivers a wide range of solubility results, presented in some wells as clear drops, others as precipitate, phase separation, or crystals. Clear drops can indicate the relative supersaturation of the sample in the drop as too low for crystallization, while precipitate can indicate the relative supersaturation as too high. If the sample has a temperature dependent solubility, the temperature of the experiment can be raised or lowered, and the effect of this change can be evaluated based upon the appearance of the drop. For example, a clear drop at room temperature moved to 10°C might result in a change in sample solubility, hence precipitate, phase separation, or even a crystal. A precipitate at room temperature, moved to 30°C may again result in a change in sample solubility, hence precipitate, phase separation, or a crystal. When a standard crystallization plate with fixed wells is used for screening, the decision to move the entire plate to a different temperature can be complicated since all the wells in the plate must be moved together. This may be less than ideal when crystals appears in one of those wells, or there is a mix of clear, precipitated, and phase sep drops where each well requires a different course of action. Each solubility result or class (clear, precipitate, phase sep, etc.) might require a unique temperature evaluation. With the Modular VDX Plate, individual wells can be removed from the frame, organized by crystallization score or solubility into a separate frame or frames, and the effect of temperature evaluated on a more discrete basis. For example, clear drops can be removed from the screen frame, complete with their respective equilibrated reservoir solution, placed into a separate frame and that newly created module can be incubated at a lower temperature. Drops with precipitate can be removed from the screen frame, organized into a new module and be incubated at an elevated temperature to see if an increase in temperature improves sample solubility and promotes crystallization.

Beyond screening, the Modular VDX Plate also offers enhanced plate flexibility and customization during optimization of preliminary crystallization experiments. Optimization experiments can be performed in Modular VDX frames, utilizing removable wells to reorganize the plate as the optimization proceeds. More promising conditions can be grouped into a single frame, reducing the actual utilized active screen space required. Less promising experiments can be archived and stored into other Modular VDX frames.

Identification of the Modular VDX Plates is simple. Frames and well sides can be labeled using a variety of color coded Tough-Tag labels.

The Modular VDX Plates are also handy for the organization of drops and wells containing crystals. Wells containing crystals suitable for diffraction analysis can be combined, stored, and carefully transported in modules, avoiding the extra baggage of wells containing clear drops and precipitate.

Just like the original VDX Plate, the Modular VDX Plate is compatible with Micro-Bridges®, Glass Sitting Drop Rods™, as well as 22 mm circle and square cover slides.

48 WELL CRYSTALLIZATION PLATES

INTELLI-PLATE 48-2 AND 48-3

APPLICATION

- Sitting Drop Crystallization

FEATURES

- SBS Footprint
- Intelli-Plate 48-2 Drop Volume:
  20 µl & 4 µl
  Reservoir: 500 µl
- Intelli-Plate 48-3 Drop Volume: 4 µl
  Reservoir: 500 µl

DESCRIPTION

HR8-152

HR8-156

The Intelli-Plate 48-2 is a 48 well sitting drop plate for optimization. The Intelli-Plate 48-2 features 6 reagent wells along the y-axis (A-F) and 8 reagent wells along the x-axis (1-8). The reagent reservoir is typically filled with 200 µl and is capable of holding between 100 and 500 µl. The optimization drop wells are arranged at the top of each well. The left sample drop well holds between 4 µl or less while the elongated sample well holds 20 µl or less.

The IntelliPlate 48-3 is a 48 well sitting drop plate for screening. The Intelli-Plate 48-3 features 6 reagent wells along the y-axis (A-F) and 8 reagent wells along the x-axis (1-8). The reagent reservoir is typically filled with 200 µl and is capable of holding between 100 and 500 µl. The screening drop wells are arranged at the top of each well. The three sample drop wells each hold between 4 µl or less.

The Hampton Research ClearSeal Film™ and Sealing Film Applicator are used to seal the Intelli-Plate when a sitting drop experiment is performed. The advanced film is a transparent, polyolefin film with clear, pressure-sensitive, silicone adhesive. The film is pre-cut to perfectly fit 96 well crystallization plates and is complete with 1 cm wide, perforated end tabs which makes handling and positioning of the film easy, without fear of fingerprints getting into the view field. The Sealing Film Applicator is a small, hand-held applicator which should be used to create a consistent film seal across the entire crystallization plate. The Intelli-Plate can also be sealed using one of the clear sealing tapes supplied in a roll format.

The height of all Intelli-Plates is 0.560 inches.

VDX48™ PLATE WITH SEALANT

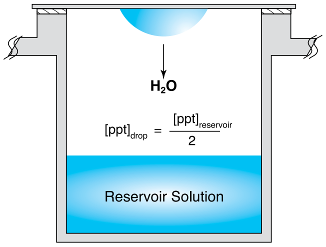
APPLICATION

- Hanging drop crystallization

FEATURES

- Sealant applied to 48 wells, ready to seal with cover slide
- Compatible with 12 mm diameter circle cover slides
- Optically clear plastic
- 128 mm x 85 mm microplate footprint

Hanging Drop Crystallization



DESCRIPTION

48 well plate with sealant for hanging drop vapor diffusion crystallization with a microplate footprint. Stackable, optically clear plastic, 48 well plates with raised covers (to allow room for cover slides)and flat bottoms for exceptional optics. Raised, wide rings around each reservoir (well) minimize cross contamination and allow each well to be individually sealed with 12 mm diameter circle cover slides. Plates are individually wrapped and supplied with applied sealant. The microplate footprint is space-saving and compatible with automated liquid handling systems. Approximate dimensions: 128 mm x 85 mm. Approximate well ID: 9 mm. Typical well volume: 100 to 300 μl.

72 WELL CRYSTALLIZATION PLATES

MICROBATCH 72 WELL PLATE (GREINER)

APPLICATION

- Microbatch crystallization

FEATURES

- Conical, flat bottom wells
- Hydrophobic or hydrophilic versions
- Compact size
- Supplied with cover

MATERIAL

- Polystyrene

DESCRIPTION

The 72 Well Microbatch Plate consists of a 6 by 12 well layout. Paraffin, Silicon, or Al's Oil is poured into the trough area of the plate, submerging all 72 wells under oil. Sample and reagent are then pipetted into each of the wells. The plate is available as a plasma-treated, hydrophilic version for screening or an untreated, hydrophobic version for optimization. The hydrophilic version gives better liquid handling with small volumes, while the hydrophobic version reduces crystal nucleation and helps to prevent the crystals from sticking to the plastic. Plate dimensions: 83.3 mm x 58.0 mm x 10.0 mm. Conical well with 11 μl drop volume. Flat bottom well diameter: 1.3 mm. Supplied with cover.

CRYSTALCLEAR STRIPS™ (DOUGLAS INSTRUMENTS)

APPLICATION

- Sitting drop vapor diffusion crystallization

FEATURES

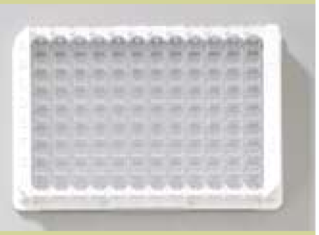
- 96 well sitting drop plate
- Concave or flat drop area
- Modular frame and well design
- One or two sample drop wells per reagent well

MATERIAL

- Polystyrene

DESCRIPTION

HR3-128



HR3-162

CrystalClear Strips 96 well sitting drop plates are suitable for both automatic and manual crystallization. They are particularly useful for screening, since they feature a space-saving microplate footprint. Sample and reagent drops (50 nl to 4 μl) are dispensed on a shelf on one side of each well. 50 to 100 μl of crystallization reagent is placed in the well. The strip is sealed with clear sealing tape. Losses by evaporation though the body of the strip and the tape are around 0.25% of the reservoir per day.

CrystalClear D (Douglas Instruments CCLEAR-D/1-10)
The CrystalClear D Strips, with indent (HR3-128) have a single depression for the sample and reagent drop on the shelf above each reservoir. This prevents hydrophobic reagents from running off the shelf into the reservoir. This version should be used for reagents and screens that contain low molecular weight alcohols and detergents. The spacing between strips is 9 mm (the regular SBS spacing). However, the spacing between sample chambers along a D strip is only 8.45 mm. Therefore, if you want to use a multichannel pipette to fill either the reservoirs or the sample wells, use a 6 or 12-channel pipette.

CrystalClear P (Douglas Instruments CCLEAR-P/1-10)
The CrystalClear P Strips, without indent (HR3-162) have a small, raised, circular platform on the shelf where samples are placed. This provides improved viewing but is not suitable for solutions containing hydrophobic reagents such as low molecular weight alcohols and detergents. However, drops below 0.2 μl (200 nl) containing alcohol (and other hydrophobic reagents) will generally work with all plates. The spacing between strips is 9 mm (the regular SBS spacing). However, the spacing between sample chambers along a P strip is only 8.45 mm. Therefore, if you want to use a multichannel pipette to fill either the reservoirs or the sample wells, use a 6 or 12-channel pipette.

CrystalClear Duo (Douglas Instruments CCLEAR-DUO/1-10)
The CrystalClear Duo Strips is a 96 well sitting drop vapor diffusion plate. The plate features SBS 9 mm spacing in both directions, which makes the plate suitable for use with all dispensing robots and in all observation systems. The plate offers low volume reagent wells for vapor diffusion with two depressions on the shelf for samples. A plate consists of a single frame and twelve strips, snapped into position, secured in the frame. Each strip contains eight wells. Each of the eight wells contains a single reagent well and two sample drop wells. Sample drop wells are flat. Frame is color coded green.

CrystalClear Strips are packaged as twelve removable 8 well strips per frame (for a total of 96 wells per frame) with ten frames (plates) per case. CrystalClear Strips are sealed using clear sealing tape or film. Approximate plate size: 12.8 cm x 8.6 cm.

CRYSTALEX™ (CORNING)

APPLICATION

- Sitting drop crystallization

FEATURES

- 96 well sitting drop plate
- Protein well shape is either conical bottom (3773) or flat bottom (3785)
- Compatible with 8 & 12 channel pipetters

MATERIAL

- Advanced optically clear polymer

DESCRIPTION

Corning® CrystalEX 96 Well Crystallization plates are designed for sitting drop vapor diffusion, high throughput protein crystallization. The plates feature 96 protein wells corresponding to 96 reagent wells. The maximum reagent well volume is 210 μl with a typical working volume of 25 to 150 μl. The maximum sample well volume is 10 μl for the conical bottom and 7 μl for the flat bottom. The flat bottom (1.5 mm diameter) sample wells provide better crystal viewing for automated imaging systems. The well surfaces are treated to be hydrophilic for improved drop mixing. Both versions are compatible with 8 and 12 channel manual pipetters, automated liquid handling work stations, and imaging systems. Both versions are manufactured from an advanced polymer with high resistance to commonly used protein crystallization reagents. The advanced polymer material provides for low-background polarization and high optical clarity so protein crystals may be viewed under polarized light with minimal background interference. Low water absorption of the polymer prevents loss of protein drop volume. The plates can be sealed using clear sealing tape or film.

CRYSTALEX™ SECOND GENERATION (CORNING)

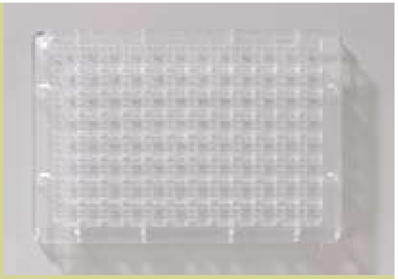
APPLICATION

- Sitting drop crystallization

FEATURES

- 96 well sitting drop plate
- Round, flat, and conical flat bottom drop well shapes
- 1, 2 or 4 microliter drop wells
- 1, 3 or 5 drop wells per reservoir
- Hydrophilicity treated or untreated
- PZero or COC plate material

DESCRIPTION



The second generation of Corning® 96 Well, sitting drop format plates are built to SBS specifications, making them well suited for high throughput crystallization and are fully compatible with robotic equipment. The plates are available in several different configurations with varying drop well shapes, plate materials, and number of drop wells per reagent well. The basic plate design is one reagent well flanked by one or three drop wells, with SBS standard spacing between the centers of adjacent well clusters. One may choose a plate with small (1 µl), medium (2 µl), or large (4 µl) drop well volumes. The choice of round, flat, or conical flat well shapes are available. The PZero polymer provides for zero background polarization and is non-birefringent. PZero plates are not treated. The COC polymer offers high chemical resistance. Both types of plastic feature improved transparency. The reservoir numbers are embossed on each individual well for easy identification. Drop well locations conform to SBS standards for robotic handling. The low-volume reagent well saves on reagent costs. The plates can be sealed using clear sealing tape or film.

CRYSTALQUICK™ 96 WELL SITTING DROP PLATE (GREINER)

APPLICATION

- Sitting drop vapor diffusion crystallization
- Hanging drop vapor diffusion crystallization with CrystalDrop™ Lid

FEATURES

- 96 well sitting drop plate
- Round or flat bottom drop wells
- Hanging drop with CrystalDrop™ Lid

MATERIAL

- Plastic

DESCRIPTION

The Greiner CrystalQuick 96 well sitting drop format plates are built to SBS specifications, making them well suited for high throughput crystallization and are fully compatible with robotic equipment. The low volume reagent well saves on reagent costs. The plates are available in round or square drop well shapes, polystyrene, LBR and hydrophobic plate materials, and a varying number of drop wells per reagent well. The CrystalQuick is available in a cyclic polyolefin low birefringence (LBR) material for polarized crystal imaging, exceptional transparency, high chemical resistance, and low water absorption. The low profile CrystalQuick version reduces the amount of space required for storage. In combination with the CrystalDrop™ Lid, the CrystalQuick plates enable simultaneous experiments using both sitting drop and hanging drop methodologies. The plates can be sealed using clear sealing tape or film.

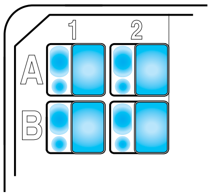
INTELLI-PLATE™ (ART ROBBINS INSTRUMENTS)

APPLICATION

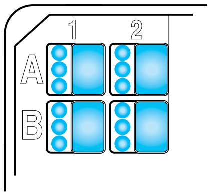
- Sitting drop crystallization

FEATURES

- 96 reservoir wells with 2 or 3 corresponding sample wells
- 96 well Intelli-Plate is compatible with 8 and 12 channel pipetters for manual set up
- Footprint and well spacing meet microplate industry standards for automation
- Intelli-Plate 96-2 well plate features a maximum fill volume of 140 µl for the reservoir well, 10 µl for the upper sample well, & 4 µl for the lower sample well
- Compatible with robotic equipment for automation
- Intelli-Plate Flat Shelf 96 well plate features a maximum fill volume of 300 µl for the reservoir well and a flat shelf for the sample drop
- Intelli-Plate 96-3 plate features a maximum fill volume of 140 µl for the reservoir well, 1 µl for the sample well
- Custom bar coding available - please inquire

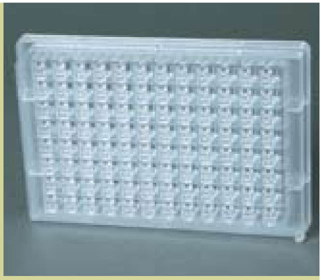


Intelli-Plate™ 96-2 well



Intelli-Plate™ 96-3 well

DESCRIPTION



The Intelli-Plate 96-2 Original crystallization plate is an optically clear plate for sitting drop vapor diffusion crystallization. It has been built to SBS specifications with 8 vertical wells versus 12 horizontal wells. This plate features two locations for sample per reservoir. The sample drop locations are located along the left side of the reagent reservoir, along the Y-axis of the plate. The sample wells are concave depressions on the ledge above the adjacent, flat bottom reagent reservoir. One sample well is located above the second sample well. The top sample well can hold 10 *μl* or less of sample. The lower sample well can hold 4 *μl* or less of sample. The reagent reservoir is typically filled with 70 *μl* of reagent and is capable of holding up to 140 *μl* of reagent. The sidewalls separating adjacent wells or reservoirs are 0.9 and 1.0 mm thick in order to offer a larger area for sealing the plate and separation of the reservoirs. The vertical wells are labeled A-H along the left side of the plate and the horizontal wells are labeled 1-12 along the top of the plate. The Intelli-Plate 96-2 is quite rigid, with virtually no torsional flex and is designed for either manual or automated pipetting. All wells have standard 9 mm spacing to conform to SBS standards. The Art Robbins Instruments catalog number for this plate is 102-0001-00.

The Intelli-Plate 96-3 well crystallization plate is an optically clear plate for sitting drop vapor diffusion crystallization. It has been built to SBS specifications with 8 vertical wells versus 12 horizontal wells. This plate features three identical locations for sample per reservoir. The sample drop locations are located along the left side of the reagent reservoir, along the Y-axis of the plate. The sample wells are concave depressions on the ledge above the adjacent, flat bottom reagent reservoir. Each identical well features a round bottom for easy crystal harvesting. Each drop well can hold up to 1 *μl* of sample. The reagent reservoir is typically filled with 70 *μl* of reagent and is capable of holding up to 140 *μl* of reagent. The sidewalls separating adjacent wells or reservoirs are 0.9 and 1.0 mm thick in order to offer a larger area for sealing the plate and separation of the reservoirs. The vertical wells are labeled A-H along the left side of the plate and the horizontal wells are labeled 1-12 along the top of the plate. All wells have standard 9 mm spacing to conform to SBS standards.

The Intelli-Plate 96 Flat Shelf crystallization plate is an optically clear plate for sitting drop vapor diffusion crystallization. It has been built to SBS specifications with 8 vertical wells versus 12 horizontal wells. This plate features a single flat shelf for sample drops. The sample drop shelves are located along the left side of the reagent reservoir, along the Y-axis of the plate. The reagent reservoir is typically filled with 100 *μl* of reagent and is capable of holding up to 300 *μl* of reagent. Maximum drop volume is 10 *μl* for the upper sample well, & 4 *μl* for the lower sample well. The sidewalls separating adjacent wells or reservoirs are 0.9 and 1.0 mm thick in order to offer a larger area for sealing the plate and separation of the reservoirs. The vertical wells are labeled A-H along the left side of the plate and the horizontal wells are labeled 1-12 along the top of the plate. The Intelli-Plate 96 Flat Shelf is quite rigid, with virtually no torsional flex and is designed for either manual or automated pipetting. All wells have standard 9 mm spacing to conform to SBS standards.

The Intelli-Plate 96-2 LVR is a Low Volume Reservoir version of the original Intelli-Plate. The Art Robbins Instruments catalog number for this plate is 102-0001-00. The plates can be sealed using clear sealing tape or film. The height of all Intelli-Plates is 0.560 inches.

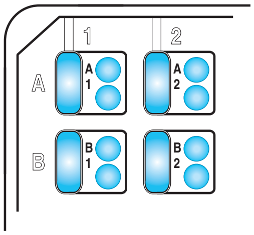
MRC 2 WELL CRYSTALLIZATION PLATE (SWISSCI)

APPLICATION

- Sitting drop crystallization

FEATURES

- Lens effect drop wells for enhanced optics
- Drop volume: 100 nl to 5 µl
- Micro-numbering alongside drop volumes
- Reservoir volume: 50 to 100 µl
- SBS format
- Rigid plate structure
- Drop well allows easier crystal harvesting
- Wide partition walls between wells improve sealing
- Developed in conjunction with the MRC Laboratory of Molecular Biology in Cambridge, United Kingdom
- Two drop wells per reservoir



MRC 2 Well Crystallization Plate

DESCRIPTION

The MRC 2 Well Crystallization Plate manufacted by Swissci is a 2 drop chamber, 96 well crystallization plate for sitting drop vapor diffusion. This plate is sometimes referred to as the Innovaplate™ SD-2 crystallography plate.

The plate was developed at the MRC Laboratory of Molecular Biology (Cambridge, United Kingdom) in collaboration with Dr. Jan Löwe. Designed to meet the stringent requirements specified by crystallographers, and made of proprietary new materials that facilitate enhanced imaging, the MRC Crystallization Plate provides easier access and removal of crystals, improved mixing of reagent and sample, and reduced sample and reagent volumes.

Easy Crystal Retrieval
Raised wide wells make the crystal mounting especially easy.

Easy Viewing
The wells are a wide conical shape and have a lens effect for perfect illumination. The micro-numbering ensures you will never get lost again when using the microscope. The optically superior polymer is UV transmissible and may be used to differentiate between salt and protein crystals.

Better Sealing
Wide partition walls between the wells give plenty of area for sealing with tape or film. No central bending occurs in this very robust structure.

Wide Range of Volumes
Typical volumes are 50 to 100 μl of reservoir and 100 nl to 5 μl drop size. The 192 optical wells offer twice the number of experiments of experimental constructions.

SBS Standard
The plate is designed to the 96 well SBS standard for all common holders and external alphanumeric identification. The MRC Crystallization Plate is suitable for centrifugation.

The plates can be sealed using clear sealing tape or film.

Innovaplate is a trademark of Innovadyne Technologies, Inc.

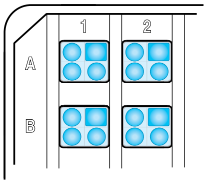
MRC 3 WELL CRYSTALLIZATION PLATE (SWISSCI)

APPLICATION

- Sitting drop crystallization

FEATURES

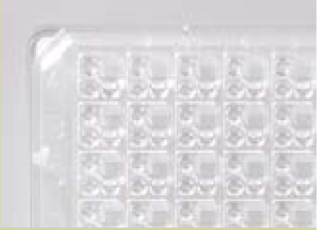
- Lens effect drop wells for enhanced optics
- Drop volume: 100 nL to 5 µl
- Micro-numbering alongside drop volumes
- Reservoir volume: 50 µl
- SBS format
- Drop well allows easier crystal harvesting
- Three drop wells per reservoir
- Low profile for easier storage



MRC 3 Well Crystallization Plate

3 circular drop wells and 1 square reservoir

DESCRIPTION



The MRC 3 Well Crystallization Plate is presented in a 96-well plate format that offers unique properties which make it ideal for both nanoliter crystallization screening and microliter optimization alike. Made from optically superior polymer (UVP) and with a new design of the wells, the plate allows easy crystal viewing and retrieval.

Easy Crystal Retrieval
Raised wide wells make the crystal mounting especially easy.

Easy Viewing
The wells are a wide conical shape and have a lens effect for perfect illumination. The micro-numbering ensures you will never get lost again (visible by microscope). The optically superior polymer is UV transmissible and may be used to differentiate between salt and protein crystals. Grown crystals are easy to identify and to remove from well due to a low-binding polymer. Plate with 3 wells for each sample, better growing security with triplicates or the ability to use well two and well three as mixing stations. Wells fill without micro-droplets jumping out due to static effects. The profile allows for easier storage. Low volume buffer well enables savings on reagents.

Better Sealing
Wide partition walls between the wells give plenty of area for good sealing with tape. No central bending occurs in this very robust structure.

Wide Range of Volumes
Typical volumes are 50 μl of reservior and 100 nl to 5 μl drop size. The 288 optical wells offer three times the number of experimental constructions.

SBS Standard
The plates are designed to the 96-well SBS standard for all common holders and external numbering (A-H, 1-12) with corner location make the plate easy to use in a robotic sampler. The 3 well plate is suitable for centrifugation.

The plates can be sealed using clear sealing tape or film.

MASTERBLOCK® 96 DEEP WELL PLATE (GREINER)

APPLICATION

- 96 Deep Well plate for crystallization screen reagents

FEATURES

- Sterile, individually sealed plates
- Polypropylene
- Seal with AlumaSeal II, Crystal Clear Sealing Film, Cap Mats, or Robolid
- SBS format

DESCRIPTION

The Greiner 780261 MASTERBLOCK is a 96 Deep Well polypropylene block (plate). Each well has a fill volume of 1.2 ml. The MASTERBLOCK is useful for holding crystallization screen reagents when using liquid handling automation or multi channel pipets. Each plate is sterile and packaged individually. Round bottom well for complete reagent recovery. ClearChoice™ virgin polypropylene resin (autoclavable to 121°C). SBS recommended dimensions. Alphanumerically coded wells with chimney-style, round well top.

Seal with AlumaSeal II, Crystal Clear Sealing Film, Cap Mats, or Robolid. Plate Lid is useful to cover the opened MASTERBLOCK when not in immediate use to minimize evaporation. MASTERBLOCK is also great for thermal sealing due to the raised chimney about each well.

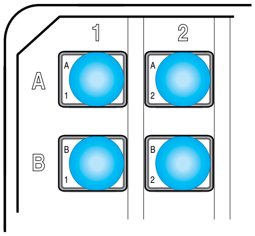
MRC UNDER OIL 96 WELL CRYSTALLIZATION PLATE (SWISSCI)

APPLICATION

- Microbatch crystallization

FEATURES

- Easy crystal retrieval
- Easy viewing
- Drop Volume 100 to 500 nl
- Oil Volume 20 µl
- SBS Standard
- Ultra low binding polymer, no static



MRC Under Oil Crystallization Plate

DESCRIPTION

The MRC Under Oil 96 Well Crystallization Plate is designed for microbatch crystallization.

The plate was developed at the MRC Laboratory of Molecular Biology (Cambridge, United Kingdom) in collaboration with Dr. Jan Löwe and colleagues.

It is a result of many years of experience in successful robotic high-throughput crystallization and combines many of the features not earlier available to the crystallographer.

The new MRC Under Oil 96 Well Crystallization Plate is designed for microbatch crystallization using paraffin, silicon oil, or a mixture of the two. Following the initial experiment, evaporation of the drop through the oil allows for second crystallization stage, enabling further crystal growth as a consequence of concentration. This is different from other experiments in that the conditions are then extreme in nature and permit new conditions to arise.

The new MRC Under Oil 96 Well Crystallization Plate offers unique properties that make it ideal for both nanoliter crystallization screening and microliter optimization alike. Made from an optically superior polymer and with a new design of the wells, the plate allows easy crystal viewing and retrieval. The advantages of the new MRC Under Oil 96 Well Crystallization Plate:

Easy Crystal Retrieval
Raised wide wells make the crystal mounting especially easy

Easy Viewing
The wells are wide conical and have a polished surface on both sides important for perfect illumination. The micro numbering ensures that you will never get lost again (visible by microscope). The optically superior polymer is even UV transmissible and may be used to differentiate between salt and crystals.

Better Sealing
Wide partition walls between the wells give plenty of area for good sealing with tape for the initial experiments of microbatch. No central bending occurs in this very robust structure.

Recommended Volumes
Typical volumes validated for these plates are 20 μl of oil with a shot through sample delivery of 100 to 500 nl. The 20 μl volume of the individual wells gives the user a wide range of macromolecular crystallization possibilities.

SBS Standard
The plates are designed to the 96 well SBS standard for all common holders ad external numbering (A - H, 1 - 12) with corner location that make the plate easy to use in a robotic sampler. The plate can also be centrifuged for better results. The unique MRC Under Oil 96 well Crystallization plate offers a new way of microbatch crystallography. The 96 wells are optically perfect, designed to observe crystals under a microscope.

Unique Polymer
The proprietary polymer is optically perfect - ultra low binding and guaranteed to have central drop location in the well. There are no static effects and thus micro-droplet jumping is avoided.

IMP@CT™ PLATE WITH RESERVOIR (GREINER)

APPLICATION

- Microbatch crystallization

FEATURES

- Conical, flat bottom wells
- Clear and black μClear®
- Double rim reservoir

MATERIAL

- Polystyrene

DESCRIPTION

The Greiner 96 Well Imp@ct Plate for microbatch crystallization has conical, flat bottom wells that promote central location of the sample drop and ease crystal harvesting. The plate has a flat, optically clear bottom. A raised perimeter wall surrounds the plate to contain Paraffin Oil, Al's Oil, or Silicon Oil. The entire inner area of the plate or each individual sample well may be filled with oil. The plate features a double rim reservoir to hold water or reagent to control and manipulate vapor diffusion from the microbatch drops. Plate dimensions: 127.76 mm x 85.48 mm x 14.4 mm. Conical flat bottom well with 8 μl drop volume. Flat bottom well diameter: 1.33 mm.

Greiner 673170 plate is clear. Greiner 673096 plate is black with clear drop area.

Plates supplied without cover. Plate Lids HR3-084 or HR3-085 (Greiner 656190) are available separately.

IMP@CT™ PLATE WITHOUT RESERVOIR (GREINER)

APPLICATION

- Microbatch crystallization

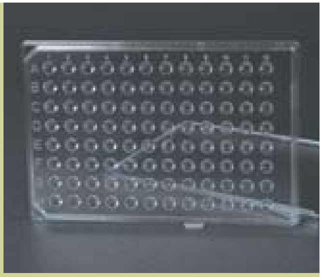
FEATURES

- Conical, flat bottom wells
- Supplied with cover
- Microplate footprint

MATERIAL

- Polystyrene

DESCRIPTION



The Greiner 673101 96 Well Imp@ct Plate has a low profile format with individual conical shaped sidewalls and a smooth, flat bottom for enhanced microscopic investigation of crystals. Conical well shape avoids spreading of the sample and reagent droplet away from the center of the well. Typical well capacity for Paraffin, Silicon, or Al's Oil is 10 to 20 μl per well. Vertical wells are labeled A-H. Horizontal wells are labeled 1-12. Stackable with supplied cover. Plate Dimensions: 127.76 mm x 85.48 mm x 8.0 mm. Conical well with 19 μl drop volume. Flat bottom well diameter: 2 mm.

MICROBATCH 96 WELL PLATE

APPLICATION

- Microbatch crystallization

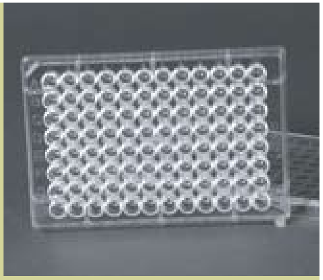
FEATURES

- 96 concave bottom wells
- Microplate footprint
- Supplied with cover

MATERIAL

- Polystyrene

DESCRIPTION



The 96 Well Microbatch Plate is an 8 by 12 well microplate with cover. Paraffin, Silicon, or Al's Oil is dispensed into each individual well. Sample and reagent are then pipetted into the wells below the oil. Individual well bottoms are "U" shaped to center the drop under oil. Oil can be rapidly (between 3 to 20 seconds) and neatly dispensed into the plate using V&P Scientific VP195B Multi-Spense or V&P Scientific VP195B1-96. After sample and reagent are dispensed under the oil using an 8 channel and single channel pipet, the plates are then centrifuged at very low speed for 5 to 10 minutes to mix and center the drops. The covered plates can be stored between 0-37°C and viewed free of condensation as the covers can be removed for viewing without drying the drops when using the microbatch method.

VAPOR BATCH 96 WELL PLATE (DOUGLAS INSTRUMENTS)

APPLICATIONS

- Sitting drop and microbatch crystallization
- Anaerobic crystallization

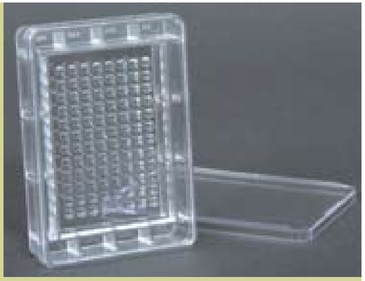
FEATURES

- 96 conical, flat bottom wells
- Supplied with cover
- Microbatch and vapor diffusion from the same plate
- Compact size
- Hydrophobic or hydrophilic versions

MATERIAL

- Polystyrene

DESCRIPTION



The Douglas Instruments Vapor Batch Plate is designed for both microbatch and sitting drop vapor diffusion crystallization. It has 96 wells in the central region of the plate and several reservoirs around the outside of the plate. Oil is placed in the central region followed by sample and reagent for a microbatch experiment. When the outside reservoirs are filled with reagent, they can be used to preserve microbatch crystals by preventing the drops from drying out. The reservoirs can also be used for common dehydrant, sitting drop vapor diffusion experiments where up to 96 wells are equilibrated against a single reagent or dehydrant. Preliminary experiments suggest this method may find more hits in screening experiments than the conventional method of using the same solution in the reservoir and the drop. Wells are individually labeled. The Vapor Batch Plate is available as a plasma-treated hydrophilic version for screening or an untreated, hydrophobic version for optimization. The hydrophilic version gives better liquid handling with small volumes, while the hydrophobic version reduces crystal nucleation and helps to prevent the crystals from sticking to the plastic. Vapor Batch Plate Holders which provide a Linbro®, VDX™, or SBS footprint are available on a special order basis. Approximate plate dimensions: 81 mm x 55 mm x 20 mm. Drop well depth: 1.8 mm. Typical drop volume: 1 to 9 μl. Maximum drop volume: 20 μl. Recommended oil fill: 2.5 ml. Recommended reagent/dehydrant volume: 8 ml.

96 WELL CRYSTALLIZATION PLATES

MULTICHANNEL PIPETTER BASIN

APPLICATIONS

- Pipet oil reservoir for microbatch crystallization
- Reagent reservoir for crystallization reagents when setting Silver Bullets screens

FEATURES

- Basin with cover
- Compatible with 8 & 12-channel pipets

MATERIAL

- Polypropylene

DESCRIPTION

The Multichannel Pipetter Basin is a polypropylene trough that allows for rapid reproduction of similar reagents or oils throughout an entire 96 Well crystallization plate. Basin comes with cover.

384 WELL CRYSTALLIZATION PLATES

CRYSTALEX™ 384 WELL FLAT BOTTOM PLATE (CORNING)

APPLICATION

- Sitting drop crystallization

FEATURES

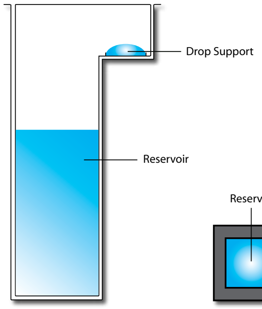
- 192 sample wells & 192 reagent wells
- Flat bottom sample well
- Low background polarization
- SBS footprint

MATERIAL

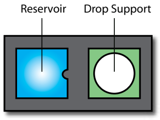
- Advanced polymer

METHODOLOGIES

- Use the CrystalEX 384 plate to screen four different reservoir solutions against the same crystallization solution to expand screening space (Newman 2005).

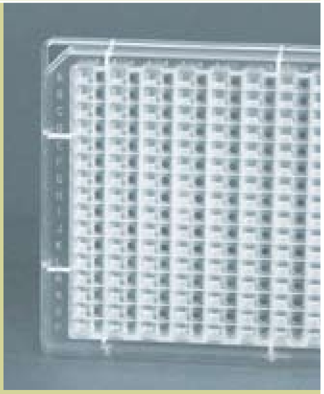


Individual side well view



Individual top well view

DESCRIPTION



The Corning® CrystalEX is designed for full automation in crystal screening and built to meet industry standards for 384 well microplate footprint and well locations. Features 192 reservoir wells with a 105 μl volume and 192 corresponding protein wells with a maximum volume of 4 μl. Typical reagent well volumes are 50 μl and sample well volumes are 1 μl. The reagent wells and sample wells are positioned to be compatible with multihead dispensing equipment (up to 96 well heads). The plate is manufactured from an advanced polymer with high resistance to commonly used solvents, including acetone, acetic acid, butanone, ethanol, iso-propanol, methanol, DMSO, nitric acid (65%), sulfuric acid (40%), hydrochloric acid (36%), and ammonia solution (33%). The advanced polymer features low background polarization and high optical clarity which allows crystals to be viewed under polarized light with minimal background interference. The low water absorption of the polymer prevents loss of protein drop volume. The plates can be sealed using Crystal Clear Sealing Tape or ClearSeal Film™. The plate is not treated.

SILICONIZED GLASS COVER SLIDES

APPLICATIONS

- Hanging, sitting or sandwich drop crystallization

FEATURES

- Siliconized, hydrophobic glass surface
- 12 mm, 18 mm, & 22 mm glass diameter
- 0.22 mm & 0.96 mm glass thickness
- Circle & square

DESCRIPTION

Siliconized glass cover slides allow a droplet to be suspended in a position which provides near optimal conditions for vapor diffusion with the surrounding reservoir solution. These siliconized glass cover slides provide a consistent, high quality finish for crystallization experiments. The hydrophobic surface produces a drop which "stands well" and does not flatten on the glass. The siliconized surface prevents the adhesion of crystals and precipitate onto the glass surface. Use vacuum grease, DC Release Compound, or immersion oil to seal cover slide to plate. Available in 12, 18 or 22 mm diameter circles and 22 mm diameter squares. Available in 0.22 mm or 0.96 mm glass thickness. The 0.96 mm thick slides are virtually unbreakable during crystallization handling.

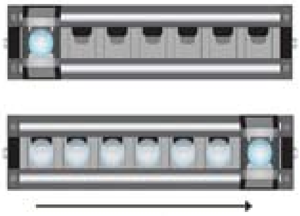
GLASS COVER SLIDE GIZMO DISPENSER

APPLICATION

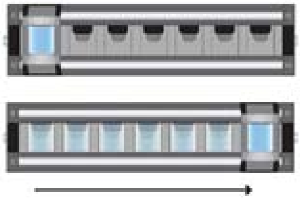
- Dispense circle or square cover slides for hanging drop crystallization

FEATURES

- Dispense siliconized or plain cover slides
- Platform displays one to six cover slides at a time for 18 and 22 mm slides
- Platform displays one to twelve cover slides at a time for 12 mm slides
- Available for 12, 18 or 22 mm diameter cover slides for either original (0.22 mm) or thick (0.96 mm) glass thickness
- Black platform for slides allows one to see if drops are clear or precipitated

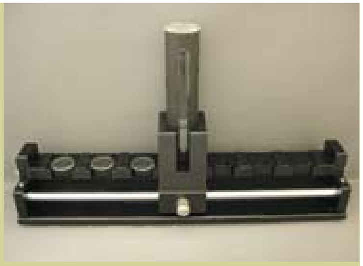


Circle Cover Slide Gizmo



Square Cover Slide Gizmo

DESCRIPTION



The Cover Slide Gizmo dispenses siliconized or plain slides for convenient drop building during hanging drop vapor diffusion crystallization. Load the cover slides into the dispenser. A clear plastic cover or sealed dispenser keeps slides clean. Slide the loaded dispenser along the platform and six cover slides are dispensed onto the platform. A black background on the platform makes for easy drop visualization as one builds the drop(s). Use finger or forceps to place the completed cover slides onto the crystallization plate.

Each Cover Slide Gizmo includes a single cover so you only need to order HR8-166 if you lose the cover for the HR8-162 or HR8-164. Manual operation, no power required.

Protein crystal grown using the Hampton Research Crystal Screen.

Enrique Lemus Fuentes, Jefe de carrera de ing. en alimentos, Universidad Tecnológica de la Mixteca.

PLAIN GLASS COVER SLIDES

APPLICATIONS

- Hanging, sitting or sandwich drop crystallization

FEATURES

- Hydrophilic glass surface
- 12 mm, 18 mm, & 22 mm glass diameter
- 0.22 mm & 0.96 mm glass thickness
- Circle & square

DESCRIPTION

Plain, non-siliconized, hydrophilic glass cover slides. Useful for hanging drop, sitting drop, and sandwich drop vapor diffusion crystallization methods. The hydrophilic surface creates a drop which is more flat than a drop on a siliconized surface. This offers enhanced imaging for very small drops. Use vacuum grease, DC Release Compound, or immersion oil to seal cover slide to plate.

OPTICLEAR™ PLASTIC COVER SLIDES

APPLICATION

- Hanging, sitting and sandwich drop crystallization

FEATURES

- 0.22 mm thickness
- RNase-free; handle with forceps to prevent contamination
- Compatible with most crystallization reagents
- Siliconization is not required
- 18 mm circle, 22 mm circle, or 22 mm square

DESCRIPTION

RNase-free, hydrophobic covers are lighter weight than glass. Plastic cover slides are ready to use without washing or siliconization. Hydrophobic working surfaces are protected with clean release liners to prevent RNase contamination. The plastic cover slides remain flat and will not curl, even at high temperatures. Plastic cover slides do not chip, crack, or break and are dust-free. Square cover slides are supplied protected in a sandwich polyethylene film. The circle cover slides are packed between fiber-free paper slips. Use vacuum grease, DC Release Compound, or immersion oil to seal cover slide to plate.

PEN-VAC®

APPLICATION

- Holding and manipulating small, flat surfaces such as glass cover slides

FEATURES

- Self-contained vacuum
- No power needed
- Compact

DESCRIPTION

PEN-VAC is a great tool for handling small, flat surfaced objects such as plain and siliconized cover slides, as well as plastic slides. Simply depress the side button, touch the tip to the object to be lifted and release the button. PEN-VAC creates a totally self-contained vacuum that lifts up to 50 grams for up to one minute. Less than an ounce, the lightweight aluminum body fits in a pocket. No power supply needed. The kit includes one PEN-VAC with 5 3/4" blue body, (3) angled and (3) straight probes with (2) each 1/8", 1/4", and 3/8" diameter blue silicone vacuum cups. It is packaged in a clear plastic storage case.

COVER SLIDE VACUUM GADGET™

APPLICATION

- Holding and manipulating small, flat surfaces such as glass cover slides

FEATURES

- Self-contained vacuum
- No power needed
- Compact

DESCRIPTION

The Cover Slide Vacuum Gadget™ allows one to pick up a single cover slide, invert the slide and gadget, rest the gadget on the bench so the slide rests as if on a pedestal, pipet the drop onto the slide, then use the gadget to place and release the slide onto the crystallization plate. The Gadget is a hand held vacuum bulb with a single Buna-N vacuum cup. Squeeze the bulb, press the vacuum cup to the slide, ease the squeeze on the bulb to create a vacuum and the slide is held in place at the end of the Gadget. When ready to position and place the slide give the Gadget a gentle squeeze to release the vacuum. Single bulb with 3/8" (9.53 mm) diameter cup.

Order Information

Cat. No.	Name	Description	Price
HR8-098	**Cover Slide Vacuum Gadget**	each	**$27.00**

PLATE STAND

APPLICATION

- Convenient plate holder

DESCRIPTION

A convenient holder for a crystallization plate, tilted at a 30° angle to comfortably view samples and pipet without strain. Equipped with a neoprene pad and rubber feet to prevent slippage. Works well with smaller, 96 well footprint plates.

Order Information

Cat. No.	Name	Description	Price

GLASS SITTING DROP RODS™

APPLICATION

- Sitting drop crystallization

FEATURES

- Perform sitting drop experiments in 24 well hanging drop plates
- Made of glass, may be siliconized
- Thermal mass stabilizes drop temperature

MATERIAL

- Optically clear glass

DESCRIPTION

Solid Glass Sitting Drop Rods with a concave depression in the top can hold up to 50 μl and fit into the well of a 24 well VDX™ Plate or Linbro® Plate. The rods can stand freely in the well, or a small amount of vacuum grease can be applied to the bottom of the rod to secure it to the plate. They also offer enhanced temperature stability due to the mass of the rod. The rods are 14 mm tall, 10 mm in diameter, and the depth of the concave depression is 2 mm. The rods are supplied without siliconization.

Order Information

Cat. No.	Name	Description	Price

MICRO-BRIDGES®

MICRO-BRIDGES®

APPLICATIONS

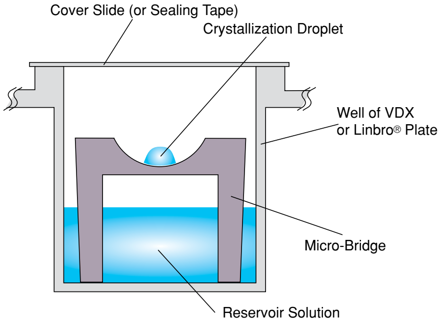
- Sitting drop crystallization
- Heavy atom soaks
- Seeding

FEATURES

- Perform sitting drop experiments in 24 well hanging drop plates
- Removable

MATERIAL

- Optically clear polystyrene



DESCRIPTION

Micro-Bridges are small devices in the shape of a bridge that are designed to carry out sitting drop vapor diffusion crystallization when placed in a VDX™ Plate or Linbro® Plate. A single Micro-Bridge fits neatly into the reservoir of a standard 24 well VDX Plate for a sitting drop crystallization experiment. Once placed inside the wells, Micro-Bridges are stable and there is no need to stick them to the wells with grease or adhesive. It is therefore possible to transfer them to other wells during or after a crystallization experiment. Why sitting drop? Placing the droplet in the indentation greatly reduces the risk of losing the protein by accident. Crystallization can be carried out in the presence of detergents and organic solvents which are compatible with polystyrene (such as MPD, iso-propanol, and ethanol). The protein drop is less affected by condensation problems. Soaking and seeding experiments can be carried out easily. Crystals can be transported more securely. Larger drop volumes can be used. Micro-Bridges have a concave indentation in the top surface of the bridge which holds the sample droplet during a crystallization experiment and prevents the droplet from spreading over a large area. Made from polystyrene, these parts are highly transparent and suitable for most crystallizations. The surface of the indentation is highly polished to facilitate the visual inspection of the drops under a microscope. The maximum drop volume for the Micro-Bridge is 35 μl. Reservoirs can be sealed with plain cover slides and vacuum grease or clear sealing tape.

MICRO-BRIDGES® POLYPROPYLENE

APPLICATIONS

- Sitting drop crystallization
- Small molecule crystallization
- Heavy atom soaks

FEATURES

- Perform sitting drop experiments in 24 well hanging drop plates
- Removable

MATERIAL

- Clarified polypropylene

DESCRIPTION

Same great Micro-Bridges, but manufactured from clarified polypropylene. These Micro-Bridges are resistant to most organic solvents, and are especially useful with crystallization experiments that involve detergents and other hydrophobic reagents. They resist drop-spreading typically observed when using reagents such as detergents, volatile organics such as iso-propanol and ethanol, and non-volatile organics such as MPD. These Micro-Bridges also resist acetone, dioxane, acetonitrile, 2,2,2 trifluoroethanol, and other aggressive organic solvents.

9 WELL GLASS PLATE

9 WELL GLASS PLATE & SANDWICH BOX SETUP

APPLICATIONS

- Sitting drop crystallization
- Seeding
- Heavy atom soaks
- Cryo transfers

FEATURES

- Siliconized, 9 well glass plates
- Concave wells
- Polystyrene box and support

MATERIALS

- Siliconized glass and polystyrene

DESCRIPTION

When setting up a Sandwich Box, one pipets 25 ml of crystallization reagent or dehydrant into the bottom of the Sandwich Box, then places a support into the box. The 9 well depression plate is placed upon the support. Drops of sample and reagent are pipetted into the depressions and the lid of the Sandwich Box is sealed closed with vacuum grease. Why Sandwich Boxes? They allow one to use very, very large drops. They are optically superior to plastic plates and glass slides, and offer different equilibration kinetics than other crystallization plates. Each of the Sandwich Box components can be washed and reused so there is little waste with the Sandwich Box Setup. These plates can be used during screening and optimization, but are best suited for final optimization and production of crystals. Since the glass plates can be removed from the boxes, crystal mounting is convenient. The siliconized 9 well depression plates are also useful for heavy atom soaks, cryo solution dilution and transfers, and seeding experiments where serial dilutions are involved. Sandwich Box Setups are available as a complete set or as individual components so one can customize the system to meet their needs. Square cover slides can be used to seal individual reservoirs but are not typically used in a crystallization setup. The Sandwich Box Setup consists of a square plastic box (4 5/16” x 4 5/16” x 1 1/8”), a polystyrene plate support, and a siliconized, glass plate (4” L x 3 3/8” W (100 mm x 85 mm)) with nine concave depressions (7/8” O.D. x 1/4” D (22 mm x 7 mm)).

SEALANTS, SEALING GREASE & OILS

IMMERSION OIL (TYPE A, B AND NVH)

APPLICATIONS

- Useful for sealing cover slides to crystallization plates
- Cryoprotection

DESCRIPTION

Useful for sealing cover slides to crystallization plates. Type A oil has low viscosity (150 centistokes), Type B has medium viscosity (1250 centistokes), Type 300 has medium/low viscosity (300 centistokes), and Type NVH has a very high viscosity (21,000 centistokes). This works well for incubations above 25°C.

DOW CORNING® VACUUM GREASE

APPLICATION

- Standard sealant for hanging, sitting, and sandwich drop vapor diffusion setups

DESCRIPTION

Dow Corning® Vacuum Grease. The standard sealant for hanging, sitting, and sandwich drop vapor diffusion setups. Stiff, non-melting, non-drying silicone sealant maintains its consistency from -40° to 260°C. Chemical-resistant and non-carbonaceous. Squeeze the grease into a 10 cc syringe fitted with a 200 μl pipet tip trimmed to desired diameter and you are ready to grease, or try the Grease Kit™.

CRYSTAL CLEAR SEALING FILM

APPLICATION

- Sealing film used to seal sitting drop crystallization experiments

FEATURES

- Fits SBS format microplates
- No special applicator required
- Optically clear

DESCRIPTION

Crystal Clear Sealing Film is an optically transparent sealing film for SBS format 24, 48, 96 and 384 well plates. The 2 mil (0.05 mm) thick, optically clear, non-fluorescing polyester film with 1 mil (0.025 mm) thick acrylic custom adhesive is designed for the convenient and secure sealing of crystallization plates. A split, optically opaque polyester backing with two end tabs assures a clean, uniform, adhesive layer and allows for easy and accurate positioning on the plate. Before use, peel off the opaque center protective polyester backing to reveal the optically clear sealing film. Film length: 5.625" Film width: 3.125"; End tabs: 0.375"; Perforations: 0.415" from edge of film; Corner radius: 3/32". DNase-, RNase-, and nucleic-acid-free, non-sterile. Recommended temperatures from -40 to +120°C.

CLEARSEAL FILM™ AND APPLICATOR

APPLICATION

- Sealing film used to seal sitting drop crystallization experiments

FEATURES

- Optically clear
- Easy to handle
- Pressure sensitive adhesive
- For best results use specially designed applicator

DESCRIPTION

ClearSeal Film fits all SBS format 96 well plates. Minimal evaporation, minimal cross-well contamination, easy to handle, and optically clear. Single coated, 2 mil (0.05 mm), clear polyolefin film with pressure-sensitive silicone-based adhesive. Supplied as a 141.3 mm x 79.4 mm film with polyester release liner (backing). Seals well to polypropylene, polystyrene, and polycarbonate plates. Compatible with aqueous and organic solvents. Suitable for use between -70 and 110°C. For best seal, the plate must be sealed with the Sealing Film Applicator. Limited shelf life. Must be used before expiration date.

The Sealing Film Applicator is a specially designed tool for the proper application of the ClearSeal Film. The design and rigid plastic allows for the application of even and consistent pressure which releases the pressure sensitive adhesive on the film to properly seal the film to the plate.

UVP HANGING DROP MRC PLATE SEAL

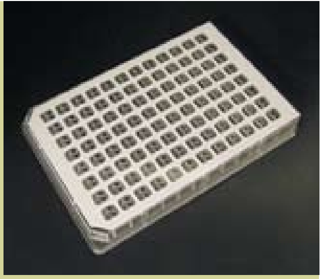
APPLICATION

- Hanging drop sealing film for MRC plates

FEATURES

- Designed for use with the 2 or 3 drop MRC plates
- UV compatible
- X-ray diffraction capability

DESCRIPTION



The new revolutionary Swissci AG UVP Hanging Drop Crystallization Plate Seal comes ready-to-use with dust free protective coating and a specialty polymer base. The seals accommodate up to 3 separate drops of protein and fit the standard 2 or 3 drop MRC plates. The product has a 100 micron thin layer of UVP specialty polymer developed for compact drop creation and ability to shoot x-ray without any noticeable diffraction.

The seals can be run with drops in the 96, 192 or 288 drop positions. The seal covers sit directly over the microplate crystallization reagent wells and are closed with a long-term resistant closing adhesive which is validated not to ingress into sample, nor lead to seal corruption. To remove an individual crystal, the seal may be peeled back or simply cut out with a scalpel. The material is very thin, although still remaining as a perfect evaporation barrier and can be sliced with a knife very easily.

The plate seals are produced in a class 10,000 clean room environment and guaranteed to be dust and scratch free. Optical quality is of the highest level available. The seals are able to be used in the UV range thus enabling the user to recognize salt from protein crystals under the ultra violet light source microscope.

CRYSTAL CLEAR SEALING TAPE

APPLICATION

- Sealing tape used to seal sitting drop crystallization experiments

FEATURES

- Optically clear
- Compatible with a wide range of crystallization reagents

Plate	1.88 inch	3 inch
Corning®		X
Cryschem™	X	
Cryschem™ 24-1 SBS		X
Douglas Instruments CrystalClear Strips™		X
Greiner		X
Intelli-Plate™		X
MRC/Swissci		X

DESCRIPTION

These optically clear tapes are compatible with protein crystallization reagents. The Crystal Clear Sealing Tapes use solvent based adhesives which are compatible with aqueous crystallization reagents.

Catalog number HR3-511 is a 1.88 inch (48 mm) wide, 3 mil tape on a 43.7 yard (40 M) roll with a 1.5 inch core and is supplied with a green dispenser/cutter.

Catalog number HR4-511 is a 1.88 inch wide, 3 mil tape on a 60 yard roll with a 3 inch core and no dispenser/cutter.

Two strips of the HR3-511 or HR4-511 will seal a Corning®, Cryschem™, CrystalClear Strip™, Greiner, Intelli-Plate™, Linbro®, MRC, VDX™ and VDXm™ plate.

Catalog number HR4-506 is a 3 inch wide, 3 mil tape on a 54.86 yard roll with a 3 inch core and no dispenser/cutter.

One strip of the HR4-506 will seal a Corning, Cryschem 24-1 SBS, CrystalClear Strip, Greiner, Intelli-Plate, MRC and VDXm plate.

See chart for tape and plate compatibility.

ALUMASEAL™ II SEALING FILM AND APPLICATOR

APPLICATION

- Sealing film used to reseal HT format screen kits

FEATURES

- Excellent seal
- Film conforms to raised chimney wells
- Easily pierceable with single or multichannel pipetters and robotic probes
- Less evaporation than clear films
- Heat & cold resistant, recommended for temperatures from -80 °C to +120 °C
- Certified DNase-, RNase-, and nucleic-acid-free
- Excellent barrier properties, virtually no reagent evaporation or drying

DESCRIPTION

A 38 μm soft non-permeable aluminum foil sealing film with strong medical-grade adhesive, AlumaSeal II sealing films eliminate the need for heat-sealing devices or mats during the resealing of reagents in Deep Well blocks. Each sealing film measures 82.6 x 142.9 mm and offers sufficient sealing area for all 96 Deep Well blocks. Length between the perforations with end tabs removed is 125.4 mm. Compared to other aluminum foils, AlumaSeal II has less tendency to roll back on itself when removing the backing paper and conforms well to the plate during application.

AlumaSeal II is a soft, pierceable adhesive film designed for the convenient and rapid sealing of reagent blocks. A multiple split backing with two end tabs allows for easy, accurate positioning and secure sealing. The use of an adhesive sealing film minimizes evaporation and helps to prevent well-to-well cross contamination in reagent blocks. AlumaSeal II films are easily pierced by pipettte tips or robotic probes or piercing tools for direct reagent recovery without significant gumming by adhesive.

ROBOLID™

APPLICATION

- Deep Well block cover for HT screens

FEATURES

- Lid dimensions are suitable for a wide range of standard microplates and liquid handling work stations
- No well-to-well contamination to ensure multiple application and removal of lid
- Silicone sealing plugs are suitable with organic solvents and low extractables
- Designed for low evaporation under standard storage conditions from -20 to 37°C

DESCRIPTION

The Robolid combines the sealing abilities of a silicone rubber mat and the automation friendliness of a polystyrene lid. Essentially, it is a silicone mat with tapered well plugs specially bonded to a polystyrene plate cover. It is compatible with a wide range of liquid handling automation. The Robolid can be used to cover a 96 Deep Well block for low evaporation, short-term storage, or to minimize evaporation or contamination during pipetting. The Robolid is compatible with the 96 Deep Well blocks used for Hampton Research HT kits such as Crystal Screen HT™, Index HT™, and SaltRx HT™.

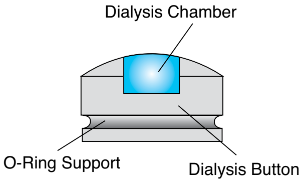
How To: Using Dialysis Buttons

Description

Crystallization by dialysis is an easy variation to the typical vapor diffusion method used to grow crystals. In the dialysis method, the sample in question is separated from the "precipitant" by a semi-permeable membrane which allows small molecules such as ions, additives, buffers, and, salts to pass but prevents biological macromolecules from crossing the membrane. Equilibration kinetics depend upon the molecular weight cutoff of the dialysis membrane, the precipitant, the ratio of the volume, the concentration of the components inside and outside of the dialysis cell, and the geometry of the cell.

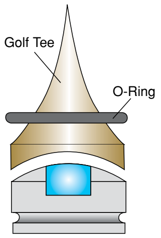
Step 1 - Place sample into dialysis cell

Pipet sample into the dialysis chamber. Amount of sample can vary depending on the size of the Dialysis Button.



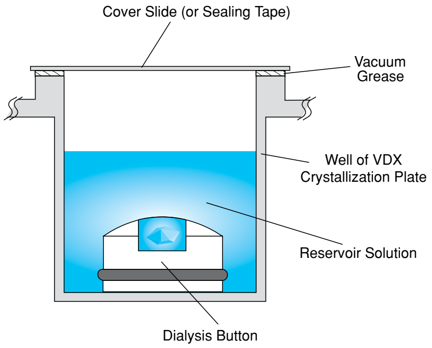
Step 2 - Placing the membrane

Choose a dialysis membrane that best suits your molecular weight cutoff of choice. Place the membrane across the top of the Dialysis Button. Using a golf tee or applicator, press down on the membrane firmly, making sure no air is trapped between the membrane and dialysis chamber. Roll the O-ring over the golf tee and onto the Dialysis Button. Make sure the O-ring is placed securely in the O-ring support, holding down the membrane.



Step 3 - Begin dialysis

Place the sealed Dialysis Button into a VDX™ Plate or Linbro® Plate. Fill the reservoir with crystallization reagent and let the dialysis begin.



Cover Slide (or Sealing Tape)
Vacuum Grease
Well of VDX Crystallization Plate
Reservoir Solution
Dialysis Button

DIALYSIS BUTTONS™

APPLICATION

- Crystallization by dialysis, protein folding, & small volume sample dialysis

FEATURES

- Low volume dialysis
- Fits in 24 well plates
- Use over and over again

DESCRIPTION

In the dialysis method, the sample in question is separated from the "precipitant" by a semi-permeable membrane which allows small reagent molecules to pass but prevents biological macromolecules from crossing the membrane.[1-3] Dialysis Buttons are either machined from transparent perspex or injection molded from polystyrene, and are the size of a small button. The sample is placed in this chamber so as to create a slight dome of liquid at the top of the button. A dialysis membrane is placed over the top of the button/sample and is held in place with an O-ring. The O-ring is held in place by a groove in the Dialysis Button. Dialysis Buttons are supplied with O-rings. The golf tee is supplied with the 5 μl to 100 μl buttons.

APPLICATOR FOR DIALYSIS BUTTONS™

APPLICATION

- Application of dialysis membrane to Dialysis Buttons

FEATURES

- Manufactured of glass
- Two sizes available
  - Small Applicator (5 - 100 µl Dialysis Buttons)
  - Large Applicator (200 & 350 µl Dialysis Buttons)

DESCRIPTION

The Applicator makes easier work of applying the dialysis membrane and O-ring to Dialysis Buttons. It positions and holds the dialysis membrane on the buttons and also allows the easy application and position of the O-ring to secure the dialysis membrane onto the Dialysis Button. The Applicator for Dialysis Buttons is manufactured of glass and is available in two sizes. The Small Applicator (HR4-348) is designed for use with 5 to 100 μl Dialysis Buttons. The Large Applicator (HR4-350) is designed for use with 200 and 350 μl Dialysis Buttons.

GRANADA CRYSTALLIZATION BOX® & CAPILLARIES

APPLICATION

- Crystallization using gels in capillaries

FEATURES

- Crystallization inside glass or quartz capillaries
- Can be used with or without gel
- Counter-diffusion or batch method

MATERIAL

- Optically clear polystyrene

figure 1

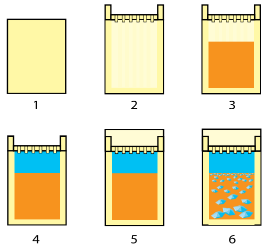

figure 2

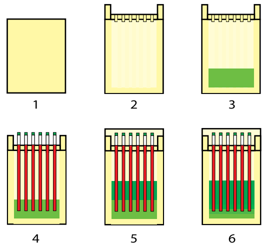

figure 3

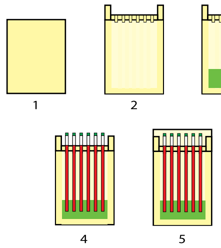

figure 4

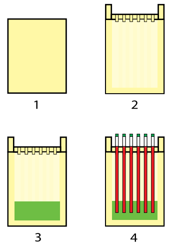
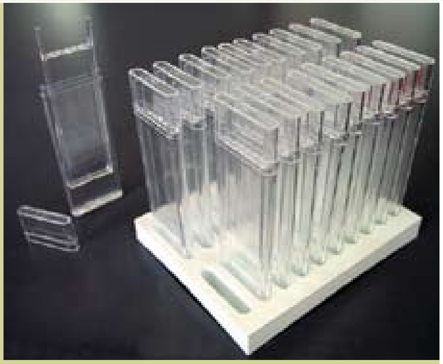


DESCRIPTION



The Granada Crystallization Box (GCB) consists of four elements made of polystyrene:

1. A reservoir to introduce the gel
2. A guide to hold capillaries
3. A cover
4. A holder to maintain the boxes

The GCB has been designed to be used in four different ways:

1. To grow crystals inside gels under diffusion-controlled mass transport (figure 1).
2. To grow crystals inside capillaries with un-gelled precipitating agent by the counter-diffusion technique (figure 2).
3. To grow crystals inside capillaries with gelled precipitating agent by the counter-diffusion technique (figure 3).
4. To grow crystals inside capillaries by the batch method (figure 4).

Capillaries and gel are not included with the Granada Crystallization Box.

The capillaries described on this page are designed for use with the Granada Crystallization Box. The capillaries are extremely thin walled. The internal diameter for these capillaries is of 0.1, 0.2 and 0.3 mm. The respective external diameters are 0.17, 0.33 and 0.40 mm. The borosilicate glass capillaries are available in four different lengths of 30, 40, 50 or 100 mm. Although the capillaries are designed for use with the Granada Crystallization Box they can also be used for general free-interface diffusion crystallization.

MICRO-TOOLS™

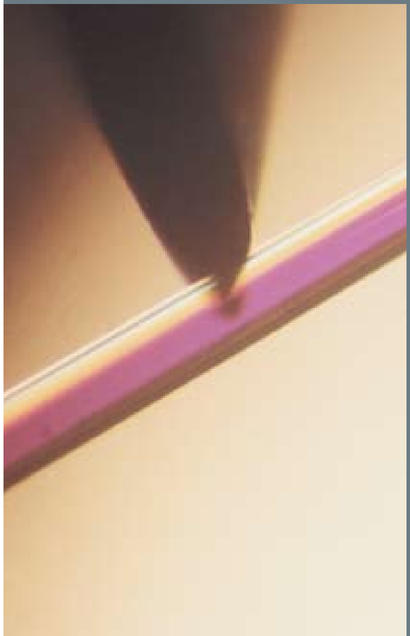
APPLICATION

- Precision instruments for crystal manipulation

FEATURES

- Made from chemical resistant, hardened tool steel
- Interchangeable tools tips

SUCCESS STORY



Crystal shown being cut using the Hampton Research Micro-Knife.

Courtesy of Lisa Edberg.

University of Alabama, Birmingham
Center for Macromolecular Crystallography

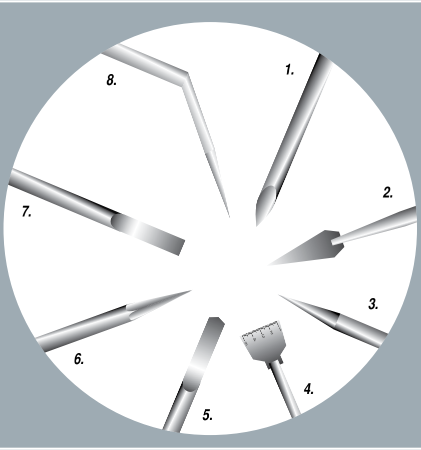
DESCRIPTION

Micro-Tools are the smallest available precision instruments for laboratory use. These tools are realistically proportioned for macromolecular and small molecule crystallization work. The high quality, precision Micro-Tools ease microscopic manipulations. The eight specifically engineered Micro-Tools are useful in a variety of applications in the crystallization lab. Eight tools, a handle and wood storage box.

Micro-Tools are designed to be versatile as well as useful for specific crystallization manipulations. For example, the Micro-Scale is very useful for measuring crystal dimensions as well as serving as a way to record the dimensions by photography for reference or publication. The Micro-Chisel and Micro-Spade are helpful for separating and splitting blade and whisker clusters during seeding or mounting. The Micro-Prober and Micro-Needle come in handy when probing precipitate or when manipulating small or large crystals for seeding as well as during mounting. The Micro-Spatula can be used to move crystals as well as split single crystals or clusters. The Micro-Scraper is helpful when working with very small crystals.

The Micro-Tools Set is indispensable during crystal observation, manipulation, seeding, and mounting. The set includes a single anodized aluminum handle which holds each of the eight unique tips, all supplied in an attractive alderwood instrument case. The case provides protective storage of the Micro-Tools as well as a convenient carrying case.

The tips are constructed from hardened tungsten steel and are resistant to most common reagents used for crystal growth. The threaded tool tips are easily interchanged with the threaded aluminum handle. The diameter of the tool shaft is 0.250 mm (0.010 inches). The actual dimension at the very tip of the tool will vary with the particular tool design.



Micro-Tool Set:
1. Micro-Scraper
2. Micro-Spatula
3. Micro-Needle
4. Micro-Scale
5. Micro-Spade
6. Micro-Knife 20°
7. Micro-Chisel
8. Micro-Prober 45°

MICRO-TOOLS II™

APPLICATION

- Precision instruments for crystal manipulation

FEATURES

- Made from chemical resistant, tungsten steel and hardened tool steel
- Interchangeable tools tips
- 8 unique tools designed to extend the original Micro-Tools set

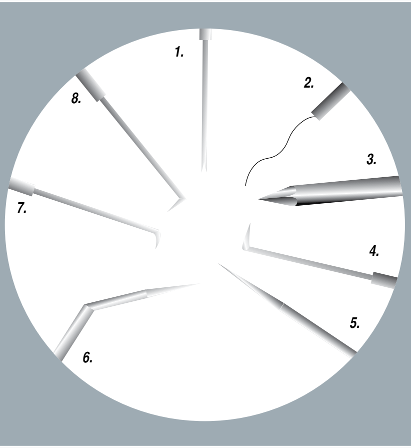
DESCRIPTION

Micro-Tools II Set is an extension to the smallest available precision instruments for laboratory use. These tools are realistically proportioned for macromolecular and small molecule crystallization work. The high quality, precision Micro-Tools II ease microscopic manipulations. The eight specifically engineered Micro-Tools II are useful in a variety of applications in the crystallization lab. Eight tools, a handle and wood storage box.

The Micro-Tools II are designed to be versatile as well as useful for specific crystallization manipulations. For example, the Micro-Manipulator is handy for manipulating long, thin blades or for separating long, thin blade clusters. Awkward positions encountered during crystal manipulation can sometimes be avoided using tools with an unusual and flexible approach angle such as the Micro-Prober 90° and the Micro-Hook 90°. Seeding experiments can be performed using the Micro-Brush. The Ultra Micro-Needles are extremely delicate tools crafted from 5 micron radius tungsten that are very handy for seeding as well as manipulations requiring a soft, fine, and controlled touch.

The Micro-Tools II Set is indispensable during crystal observation, manipulation, seeding, and mounting. The set includes a single anodized aluminum handle which holds each of the eight unique tips, all supplied in an attractive alderwood instrument case. The case provides protective storage of the Micro-Tools as well as a convenient carrying case.

The tips are constructed from hardened tungsten steel and are resistant to most common reagents used for crystal growth. The threaded tool tips are easily interchanged with the threaded aluminum handle. The diameter of the tool shaft is 0.250 mm (0.010 inches). The actual dimension at the very tip of the tool will vary with the particular tool design.



Micro-Tool II Set :
1. Manipulator
2. Micro-Brush
3. Micro-Knife 45°
4. Micro-Prober 90°
5. Ultra Micro-Needle, straight, tungsten, 5 micron radius
6. Ultra Micro-Needle, bent 30°, tungsten, 5 micron radius
7. Micro-Hook 90°
8. Ultra Micro-Needle, bent 90°, tungsten, 5 micron radius

FORCEPS

ULTRA-FINE FORCEP

FEATURES

- Length - 115 mm
- Tip - 9.5 mm to point

DESCRIPTION

High quality, precision straight forceps with an extra fine point. Smooth, non-serrated tip and handle. Great for mounting CryoLoops.

Order Information

Cat. No.	Name	Description	Price
HR4-855	Ultra-Fine Forcep	each	$10.00

SLIDE-TENSION FORCEP

FEATURES

- Length - 150 mm
- Tip - 10.3 mm to point

DESCRIPTION

Straight forcep with adjustable "locking" tension bar. Increase the width of the tip opening by setting the bar to the desired position. Slide bar can be positioned to "lock" forceps and hold cover slides, CryoLoops, MicroTubes, and other small parts.

Order Information

Cat. No.	Name	Description	Price
HR4-857	Slide-Tension Forcep	each	$8.00

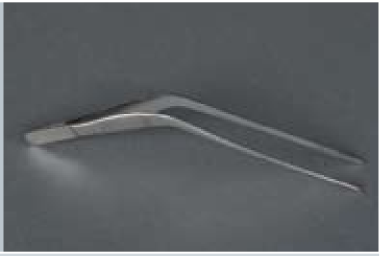
45° ANGLED FORCEP

FEATURES

- Length - 137 mm
- Tip - 2.5 mm to point

DESCRIPTION

All purpose angled forcep with blunt end. Tip has serration for firm grip. Good for retrieving. 45° angle makes for easy manipulation. Especially nice for flipping cover slides. Has serrated non-slip handle.



Order Information

Cat. No.	Name	Description	Price
HR4-859	45° Angled Forcep	each	$10.00

30° TIP ANGLED FORCEP

FEATURES

- Length - 119 mm
- Head Length - 11.5 mm
- Head Width - 6.1 mm

DESCRIPTION

Smooth, wide, angled, flat tip that will leave delicate items undamaged, unlike tweezers with sharp points. Tip is angled down 30° from the handle. Has serrated, non-slip handle. Good for handling cover slides and filter paper.

Order Information

Cat. No.	Name	Description	Price
HR4-861	30° Tip Angled Forcep	each	$8.00

SMALL FORCEP

FEATURES

- Length - 140 mm
- Tip Width - 2.5 mm

DESCRIPTION

All purpose straight forcep with blunt end. Tip has serrated surface for firm grip. Good for retrieving. Has serrated non-slip handle.

Order Information

Cat. No.	Name	Description	Price
HR4-863	**Small Forcep**	each	**$9.00**

MEDIUM FORCEP

FEATURES

- Length - 200 mm
- Tip Width - 2.5 mm

DESCRIPTION

All purpose straight forcep with blunt end. Tip has serrated surface for firm grip. Good for retrieving. Has serrated non-slip handle.

Order Information

Cat. No.	Name	Description	Price
HR4-865	**Medium Forcep**	each	**$13.00**

EXTRA LARGE FORCEP

FEATURES

- Length - 300 mm
- Tip Width - 2.5 mm

DESCRIPTION

All purpose straight forcep with blunt end. Tip has serrated surface for firm grip. Good for retrieving. Has serrated non-slip handle.

Order Information

Cat. No.	Name	Description	Price
HR4-869	**Extra Large Forcep**	each	**$10.00**

FORCEPS

STRAIGHT MICROFORCEP

FEATURES

- Length - 113 mm
- Tip Length - 31 mm
- Tip Width - 3.1 mm to point

DESCRIPTION

Ultra-thin, smooth, pointed tip for very precise work. Great for retrieving or holding small parts. Smooth, non-serrated handle and tip.

Order Information

Cat. No.	Name	Description	Price
HR4-871	**Straight Microforcep**	each	**$13.00**

45° TIP ANGLED FORCEP

FEATURES

- Length - 113 mm
- Tip Length - 10.9 mm
- Tip Width - 3.5 mm to point

DESCRIPTION

Straight forceps with angled tip. Easy to use forceps when space is limited. Tip is slanted at a 45° angle. Smooth, non-serrated handle and tip.

Order Information

Cat. No.	Name	Description	Price
HR4-875	**45° Tip Angled Forcep**	each	**$8.00**

CURVED TIP MICROFORCEP

FEATURES

- Length - 113 mm
- Tip Length - Curved to point

DESCRIPTION

Ultra-thin, smooth, pointed tip for very precise work. Great for retrieving or holding small parts. Smooth, non-serrated handle and tip.

Order Information

Cat. No.	Name	Description	Price
HR4-879	**Curved Tip Microforcep**	each	**$9.00**

ANGLED TIP LOCKING FORCEP

FEATURES

- Length - 156 mm
- Tip Length - 18 mm
- Tip Width - 1.7 mm

DESCRIPTION

All purpose angled tip forcep. Tip has serrated surface for firm grip. Good for retrieving. When closed and squeezed, forcep locks to clamp and hold item in place. Lock is released by moving "lock" toward tip with thumb. Serrated, non-slip handle. Angled for easy manipulation.

Order Information

Cat. No.	Name	Description	Price
HR4-881	**Angled Tip Locking Forcep**	each	**$13.00**

LOCKING FORCEP

FEATURES

- Length - 156 mm
- Tip Width- 1.7 mm

DESCRIPTION

All purpose straight forcep. Tip has serrated surface for firm grip. Good for retrieving. When closed and squeezed, forcep locks to clamp and hold item in place. Lock is released by moving “lock” toward tip with thumb. Serrated, non-slip handle.

Order Information

Cat. No.	Name	Description	Price
HR4-883	**Locking Forcep**	each	**$13.00**

CRYSTAL PROBE™

APPLICATIONS

- Crystal manipulation
- Seeding

FEATURES

- Stainless steel probe with plastic handle

DESCRIPTION

Disposable Crystal Probe manipulators made from a 0.12 mm x 30 mm stainless steel, pointed-end probe attached to a 20 mm plastic handle. Useful for breaking apart blade clusters and general crystal manipulation. Small size and disposable format makes them convenient for trips to the synchrotron.

Order Information

Cat. No.	Name	Description	Price
HR4-217	**Crystal Probe**	12 pack	**$15.00**

CRYSTAL PENCIL™

APPLICATIONS

- Crystal manipulation
- Seeding
- Crystal mounting

DESCRIPTION

Useful for manipulating crystals for seeding and cryocrystallography. The 0.7 mm tip accepts the Hampton Research Mounted CryoLoops™ or MicroTubes™ with your own cryoloop which creates an easy to hold, comfortable, and convenient tool for manipulating crystals. CryoLoops, MicroTubes, and Mounted CryoLoops sold separately.

Order Information

Cat. No.	Name	Description	Price
HR4-835	**Mechanical Crystal Pencil**	each	**$3.00**

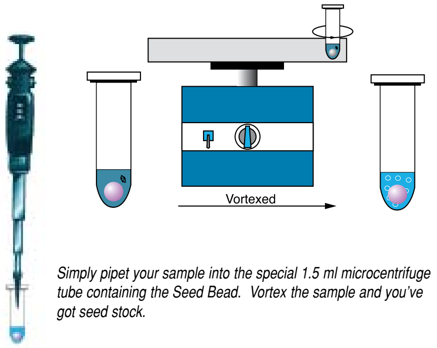
SEED BEAD™

APPLICATION

- Generate seeds of protein crystals

FEATURES

- Easily generate consistent seed stocks
- Use serial dilution to control the number of seeds introduced into the drop



Simply pipet your sample into the special 1.5 ml microcentrifuge tube containing the Seed Bead. Vortex the sample and you've got seed stock.

DESCRIPTION

The Seed Bead kit is used to create a seed stock for performing subsequent seeding experiments. The Seed Bead kit contains 24 Seed Beads manufactured from PTFE, individually contained in a special 1.5 ml microcentrifuge tube.

Seeding allows one to grow crystals in the metastable zone. Crystallization in this zone provides control, reproducibility and an improved likelihood of a successful crystallization experiment. Also, crystals can grow from seeds but cannot spontaneously nucleate. By placing a seed or solution of seeds in a drop which is saturated to the metastable zone, one can use the seeds to grow larger single crystals. By controlling the number of seeds introduced into the drop, one can control the number of crystals grown. It is not practically possible to measure and know the number of seeds introduced to a drop, but by performing serial dilutions from a concentrated seed stock, one can control the number of crystals grown in the drop.

Using the Seed Bead kit, one can create crystal seed stock for subsequent seeding experiments. Crystals are placed in the microcentrifuge tube with the PTFE Seed Bead and either vortexed or sonicated to generate a seed stock. Then by performing serial dilutions, one can control the number and size of crystals in the experiment.

The Seed Bead kit is useful for the preparation of seed stocks for automated and semi-automated microseeding (D'Arcy 2007, Harlos 2008).

Each kit contains 24 special microcentrifuge tubes with Seed Beads. Crystallization accessories are sold separately.

SEEDING TOOL

APPLICATION

- Streak Seeding

FEATURES

- Natural fiber
- Built-in handle/cover

DESCRIPTION

During streak seeding, one touches the Seeding Tool to crystalline material to dislodge, remove and transfer small crystals (seeds) to a drop that will support the growth of potentially larger and more perfect crystals. A seed can provide a template on which additional macromolecules can assemble and under the proper conditions, grow to form a large single crystal. Using seeding can avoid problems associated with growing crystals from spontaneous nucleation. Seeds can grow into larger crystals in the metastable region of the solubility curve, which is a region of lower, relative supersaturation. One can also streak seed from phase separation or amorphous material as a diagnostic to confirm whether the material is crystalline. The Seeding Tool is a 1 cm natural fiber attached to a stainless steel pin and plastic handle. The Seeding Tool is supplied with a cover to protect the fiber and when the cover is placed on the back side of the Seeding Tool, it makes an excellent handle.

CHELATING RESIN™

APPLICATION

- Remove trace metals from water, reagents, & samples

FEATURES

- Scavenge multivalent metal ion contaminants
- Remove nickel from sample following purification over a nickel column

DESCRIPTION

Chelating Resin can be used to remove trace metals from water, reagents, and macromolecular samples[1-3].

Chelating Resin has a high preference for mercury, copper, nickel, lead, zinc, cobalt, cadmium, iron, manganese, barium, calcium, strontium, and magnesium. Its selectivity for divalent ions over monovalent ions is high (5,000:1) and it has a very high attraction for transition metals, even in concentrated salt solutions. The resin will scavenge multivalent metal ion contaminants without altering the concentration of nonmetallic ions. In most cases the resin does not have any effect on protein concentration or activity.

Chelating Resin is a high purity, 100-200 mesh resin. This resin is a styrene divinylbenzene copolymer containing paired iminodiacetate ions which act as chelating groups in binding polyvalent metal ions. The nominal capacity is 2.0 meq/dry gram or 0.4 meq/ml resin bed. The density is 0.65 g/ml. The resin can be classed with weakly acidic cation exchange resins due to the presence of carboxylic acid groups but differs from ordinary exchange resins due to its high selectivity for metal ions and high bond strength. The resin is stable over the entire pH range and functionally active from pH 2 to 14. The resin is stable for at least two years when stored in the original sealed container at 23°C.

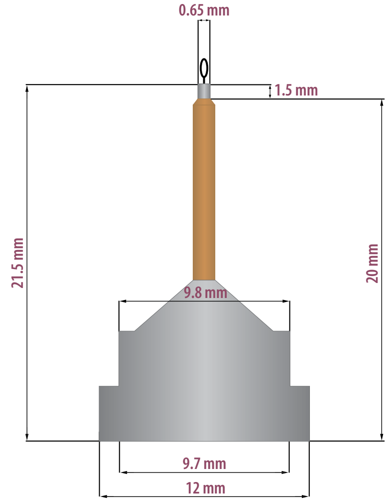
CRYSTALCAP™ COPPER MAGNETIC HT

APPLICATION

- Cryocrystallography

FEATURES

- Specially designed vial with magnetic ring
- Cap magnetically attaches to vial
- Copper jacket to reduce icing on MicroTube
- Vented vial sold separately
- No threads
- Bar coded, color coded, alphanumeric, magnetic cap
- Assembled with Mounted CryoLoops, ready-to-use; vials sold separately
- Cap features a flat ledge used by grippers such as SSRL Stanford Automated Mounting System (SAM)



CrystalCap Copper Magnetic HT

DESCRIPTION

CrystalCap Copper Magnetic HT is designed to prevent ice formation along the copper pin/MicroTube™ in a cryostream where the flow is positioned perpendicular, at an angle, or non-collinear to the MicroTube. The CrystalCap Copper Magnetic HT is a non-threaded, 1.8 ml (approximate) cryo vial storage container with a specially engineered cap/pin for cryocrystallography. Each cap is manufactured from an alloy base which allows the cap to be magnetically secured to a magnetic base in the goniometer head. Into the alloy cap is threaded and bonded a solid, 3 mm diameter copper pin. The end of the copper pin is machined to an aerodynamic 60° and is assembled with a MicroTube and CryoLoop. A ring magnet is molded into the top end of the vial so that when the cap is positioned in the vial, the ring magnet holds the cap on the vial during cryogenic storage. The vial has two holes for venting. The 18 mm designates the distance between the top of the copper pin and the bottom of the CrystalCap Copper Magnetic where contact is made with the magnetic base.

For crystal transfer under cryo temperature use the 18 mm CryoTong (catalog number HR4-637 for the 110 mm overall tool length or catalog number HR5-112 for the 180 mm overall tool length).

The cap features a two dimensional bar coded and alphanumeric 16 x 16 data matrix. Each cap is also color coded.

HR8-181 CrystalCap Copper Magnetic HT is a two dimensional bar coded and alphanumerically labeled cap with copper pin; no Mounted CryoLoop and no vial.

Note: Caps with Mounted CryoLoops are sold without vials. Vials sold separately.

Color Coded Cap	CryoLoop Size

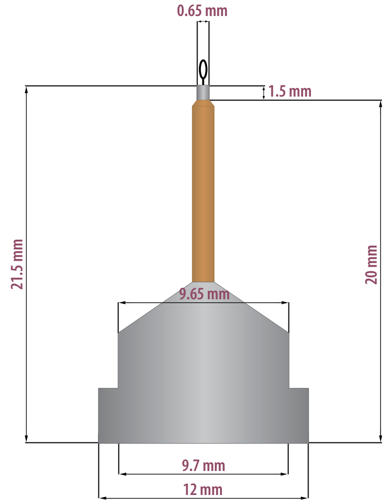
CRYSTALCAP™ COPPER MAGNETIC ALS HT

APPLICATION

- Cryocrystallography

FEATURES

- Specially designed vial with magnetic ring
- Cap magnetically attaches to vial
- Copper jacket to reduce icing on MicroTube
- Vented vial sold separately
- No threads
- Bar coded, color coded, alphanumeric, magnetic cap
- Assembled with Mounted CryoLoops, ready-to-use; vials sold separately
- Compatible with ALS style sample handlers, mounters
- Cap has ledge free, conical shape used by grippers in ALS - style automounters. For use at LBNL Berkeley Center for Structural Biology, with the PXRR automounter at Brookhaven NSLS, and at CHESS



CrystalCap Copper Magnetic ALS HT

DESCRIPTION

CrystalCap Copper Magnetic ALS HT is designed to prevent ice formation along the copper pin/MicroTube™ in a cryostream where the flow is positioned perpendicular, at an angle, or non-collinear to the MicroTube. The CrystalCap Copper Magnetic ALS HT is a non-threaded, 1.8 ml (approximate) cryo vial storage container with a specially engineered ALS compatible cap/pin for cryocrystallography. Each ALS style cap is manufactured from an alloy base which allows the cap to be magnetically secured to a magnetic base in the goniometer head. Into the alloy cap is threaded and bonded a solid, 3 mm diameter copper pin. The end of the copper pin is machined to an aerodynamic 60° and is assembled with a MicroTube and CryoLoop or is available without a MicroTube and CryoLoop (HR8-182). A ring magnet is molded into the top end of the vial so that when the cap is positioned in the vial, the ring magnet holds the cap on the vial during cryogenic storage. The vial has two holes for venting. The 18 mm designates the distance between the top of the copper pin and the bottom of the CrystalCap Copper Magnetic where contact is made with the magnetic base.

For crystal transfer under cryo temperature use the 18 mm CryoTong (catalog number HR4-637 for the 110 mm overall tool length or catalog number HR5-112 for the 180 mm overall tool length).

The cap features a two dimensional bar coded and alphanumeric 16 x 16 data matrix. Each cap is also color coded.

HR8-182 is a CrystalCap Copper Magnetic ALS HT cap only. No MicroTube, no CryoLoop, no vial.

Note: Caps with Mounted CryoLoops are sold without vials. Vials available separately.

CRYSTALCAP™ HT SYSTEMS

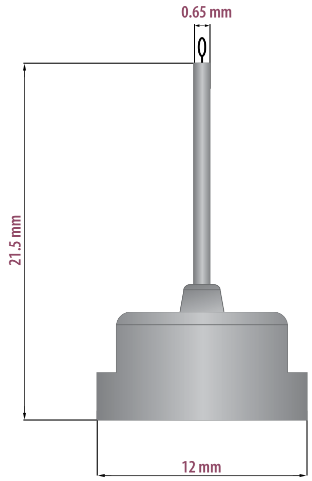
CRYSTALCAP™ HT (SPINE)

APPLICATION

- Cryocrystallography

FEATURES

- Specially designed vial with magnetic ring
- Cap magnetically attaches to vial
- Vented vial sold separately
- No threads
- Bar coded, color coded, alphanumeric, magnetic cap
- Assembled with Mounted CryoLoops, ready-to-use; vials sold separately
- Compatible with automated sample handlers
  - SPINE sample changer
  - ALS style sample mounters
  - Brookhaven National Lab PXRR automounter
  - ESRF automated sample changer



CrystalCap HT

DESCRIPTION

The CrystalCap HT is a complete crystal mount for manual and automated cryocrystallography. The cap supports the MicroTube and CryoLoop and is made from a corrosion resistant magnetic alloy. Chamfered edges on the cap avoid potential blocking during transfers. The cap design minimizes material to reduce the cooling/melting/drying temperature cycle when the sample holder is transferred. The cap features a two dimensional, bar coded and alphanumeric 16 x 16 data matrix. The alloy cap, alloy MicroTube, and synthetic CryoLoop feature an overall sample holder length of 22 mm (measured from the base of the cap to beam position). The magnetic vial, which is sold separately, is vented, features chamfered edges for enhanced cap positioning and a magnetic alloy bottom for stability. The CrystalCap HT is compatible with numerous commercial and academic automated sample handling systems. It is available as individual components (cap only, vial only, or cap and vial) or as an assembled crystal mount system (cap, MicroTube, and CryoLoop). The CryoLoop is a 20 micron diameter, synthetic material.

For crystal transfer under cryo temperature use the 18 mm CryoTong (catalog number HR4-637 for the 110 mm overall tool length or catalog number HR5-112 for the 180 mm overall tool length).

HR8-094 is the Crystal Cap HT cap only, no color code, no two dimensional bar code, no white background on bottom of cap, no alphanumeric side labeling, and is the cap only, without Mounted CryoLoop.

Note: Caps with Mounted CryoLoops are sold without vials. Vials available separately.

Color Coded Cap	CryoLoop Size
Red	0.025 - 0.05 mm
Green	0.05 - 0.1 mm
Yellow	0.1 - 0.2 mm
Blue	0.2 - 0.3 mm
Blue/Red	0.3 - 0.4 mm
Green/Red	0.4 - 0.5 mm
Yellow/Red	0.5 - 0.7 mm
Yellow/Green	0.7 - 1.0 mm

The CrystalCap HT is compatible with the SPINE sample changer, ALS style sample mounters, the Brookhaven National Lab PXRR automounter, and the ESRF automated sample changer.

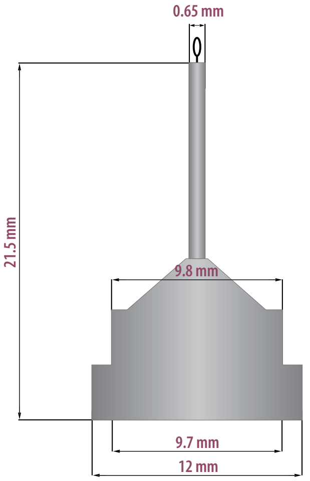
CRYSTALCAP™ MAGNETIC

APPLICATION

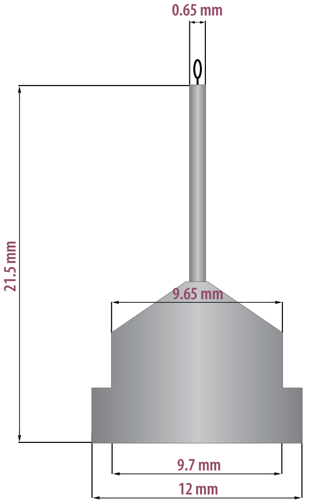
- Cryocrystallography

FEATURES

- Magnetic cap
- Specially designed vial with magnetic ring
- Cap magnetically attaches to vial
- Vented vial
- No threads
- Vial without magnetic base

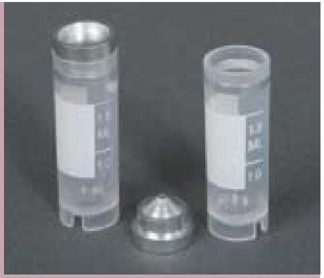


CrystalCap Magnetic



CrystalCap Magnetic ALS

DESCRIPTION



The CrystalCap Magnetic is a non-threaded, 1.8 ml (approximate) cryo vial storage container with a specially engineered cap for cryocrystallography. Each cap is manufactured from an alloy base which allows the cap to be magnetically secured to a magnetic base in the goniometer head. A ring magnet is molded into the top end of the vial so that when the cap is positioned in the vial, the ring magnet holds the cap on the vial during cryogenic storage. The tip of the metal cap is ready to accept a MicroTube™ and CryoLoop™ or Mounted CryoLoop™. CrystalCap Magnetic is available with or without a vial. The vial contains two small holes for venting.

CrystalCap Magnetic ALS (HR4-779) is compatible with ALS style sample changers.

In the comparison image above, the CrystalCap Magnetic (notice ledge at bottom of taper) appears on the left while the CrystalCap Magnetic ALS (no ledge at bottom of taper) appears on the right. Both cap styles can accept and use the same CrystalCap Magnetic Vial.

Brookhaven National Lab PXRR automounter is compatible with the CrystalCap Magnetic ALS.

The automounter at the Berkeley Center for Structural Biology at Lawrence Berkeley National Labs is compatible with the CrystalCap Magnetic ALS.

ALS style sample mounters accept the CrystalCap Magnetic ALS.

The ESRF automated sample changer accepts the Hampton Research CrystalCap Magnetic with an 18 mm mounted cryoloop.

CRYSTALCAP™ MAGNETIC SYSTEMS

CRYSTALCAP™ COPPER MAGNETIC

APPLICATION

- Cryocrystallography

FEATURES

- Magnetic cap
- Specially designed vial with magnetic ring
- Cap magnetically attaches to vial
- Copper jacket to reduce icing on MicroTube
- Vented vial
- No threads
- Vial without magnetic base

DESCRIPTION

CrystalCap Copper Magnetic is designed to prevent ice formation along the copper pin/MicroTube™ in a cryostream where the flow is positioned perpendicular, at an angle, or non-collinear to the MicroTube. The CrystalCap Copper Magnetic is a non-threaded, 1.8 ml (approximate) cryo vial storage container with a specially engineered cap/pin for cryocrystallography. Each cap is manufactured from an alloy base which allows the cap to be magnetically secured to a magnet base in the goniometer head. Into the alloy cap is threaded and bonded a solid, 3 mm diameter copper pin. The end of the copper pin is machined to an aerodynamic 60° and has a 0.65 mm opening designed to accept a 10 mm MicroTube and CryoLoop™ or Mounted CryoLoop™ snapped at the 10 mm mark to properly position the CryoLoop in the beam. A ring magnet is molded into the top end of the vial so that when the cap is positioned in the vial, the ring magnet holds the cap on the vial during cryogenic storage. The tip of the metal cap is ready to accept a MicroTube and CryoLoop or Mounted CryoLoop. The vial has two holes in the vial for venting. The sampler pack contains two of each copper pin length (10, 12, 14, 16, 18, 21, 24 mm). The length is the distance between the top of the copper pin and the bottom of the CrystalCap Copper Magnetic where contact is made with the magnetic base.

The ESRF automated sample changer accepts the Hampton Research CrystalCap Copper Magnetic 18 mm.

CRYSTALCAP™ SYSTEMS

CRYSTALCAP™

APPLICATION

- Cryocrystallography

FEATURES

- Cap threads to vial
- Vented cap
- Magnetic base plate in cap for attachment to a magnetic base
- Cap accepts 0.65 mm diameter MicroTube or Mounted CryoLoop

DESCRIPTION

The CrystalCap is a threaded, 1.8 ml cryo vial storage container with a specially engineered cap for cryocrystallography. Each cap contains a magnetic base plate which allows the CrystalCap to be magnetically secured to a magnetic base in the goniometer head. The opposite end of the CrystalCap is ready to accept a MicroTube and CryoLoop or Mounted CryoLoop. The CrystalCap lid is vented to allow cryogen to pass in and out of the container. The CrystalCap is aerodynamically efficient to minimize ice buildup.

CRYSTALCAP™ - COLORED

APPLICATION

- Cryocrystallography

FEATURES

- Cap threads to vial
- Caps are colored to make identification & organization easier
- Vented cap
- Magnetic base plate in cap for attachment to a magnetic base
- Cap accepts 0.65 mm diameter MicroTube and Mounted CryoLoop

DESCRIPTION

The CrystalCap is now available is six different colors: Red, Orange, Yellow, Green, Blue, and Pink. The vial container remains clear. Only the cap lid is colored. Same CrystalCap features are color coded to make identification, storage, and recovery faster, easier, and less confusing.

The CrystalCap is a threaded, 1.8 ml cryo vial storage container with a specially engineered cap for cryocrystallography. Each cap contains a magnetic base plate which allows the CrystalCap to be magnetically secured to a magnetic base in the goniometer head. The CrystalCap lid is vented to allow cryogen to pass in and out of the vial container.

CRYSTALCAP™ COPPER

APPLICATION

- Cryocrystallography

FEATURES

- Cap threads to vial
- Copper jacket to reduce icing on MicroTube
- Vented cap
- Zinc plated steel base plate for attachment to a magnetic base

DESCRIPTION

CrystalCap Copper is designed to prevent ice formation when using the MicroTube™ in a cryostream where the flow is positioned perpendicular, at an angle, or non-collinear to the MicroTube. The CrystalCap Copper uses a 1.8 ml cryo vial storage container and a cap which contains a sealed, zinc-plated metal core which allows the CrystalCap Copper to be secured to a magnetic platform on the goniometer head. Threaded into the metal base is a solid, 3 mm diameter copper pin. The end of the copper pin is machined to an aerodynamic 60° and has a 0.65 mm opening to accept ONLY a 10 mm MicroTube and CryoLoop™ or Mounted CryoLoop™ snapped at the 10 mm mark. The CrystalCap Copper lid is vented to allow cryogen to pass in and out of the container. The length (10, 12, 14, 16, 18, 21, or 24 mm) is the distance between the top of the copper pin and the bottom of the CrystalCap Copper where contact is made with the magnetic base.

MOUNTED CRYOLOOP™ - 20 MICRON

APPLICATION

- Cryocrystallography

FEATURES

- Synthetic CryoLoop on stainless steel MicroTube
- MicroTube specially engineered with EasySnap notches
- Complete range of loop diameters from 0.025 - 1.0 mm

DESCRIPTION

Mounted CryoLoops with 20 micron diameter nylon. These nylon loops are pre-staked to hollow, stainless steel MicroTubes™ that are used to mount, freeze, and secure the crystal during cryocrystallographic procedures and x-ray data collection. The MicroTube is 24 mm in length and is specially engineered with EasySnap™ notches at the 10, 12, 14, 18, and 21 mm measures. To obtain the desired length of MicroTube, simply snap the MicroTube at the desired length and stake it to the CrystalCap Magnetic™ or CrystalCap Copper Magnetic™. These nylon loops show minimal diffraction, are thin for fast freezing, strong, and aerodynamic. Most data collection geometries prefer or require a 22 mm length between the base of the cap and the beam. For a 22 mm overall length using the CrystalCap, CrystalCap Magnetic and CrystalCap HT, snap the MicroTube at the second notch from the bottom. Snap the MicroTube at the fifth notch from the bottom (notch closest to the CryoLoop) and attach to an 18 mm CrystalCap Copper or CrystalCap Copper Magnetic to create a 22 mm length between the base of the cap and the beam.

MOUNTED CRYOLOOP™ - 10 MICRON

APPLICATION

- Cryocrystallography

FEATURES

- Synthetic CryoLoop on stainless steel MicroTube
- MicroTube specially engineered with EasySnap notches
- Complete range of loop diameters from 0.05 - 0.5 mm

DESCRIPTION

Mounted CryoLoops with 10 micron diameter nylon. These nylon loops are pre-staked to hollow, stainless steel MicroTubes™ that are used to mount, freeze, and secure the crystal during cryocrystallographic procedures and x-ray data collection. The MicroTube is 24 mm in length and is specially engineered with EasySnap™ notches at the 10, 12, 14, 18, and 21 mm measures. To obtain the desired length of MicroTube, simply snap the MicroTube at the desired length and stake it to the CrystalCap Magnetic™ or CrystalCap Copper Magnetic™. These nylon loops show minimal diffraction, are thin for fast freezing, strong, and aerodynamic. The 10 micron Mounted CryoLoop shows less background diffraction than the 20 micron Mounted CryoLoop. Please note that the 10 micron Mounted CryoLoops are very flexible due to their small diameter. Most data collection geometries prefer or require a 22 mm length between the base of the cap and the beam. For a 22 mm overall length using the CrystalCap, CrystalCap Magnetic and CrystalCap HT, snap the MicroTube at the second notch from the bottom. Snap the MicroTube at the fifth notch from the bottom (notch closest to the CryoLoop) and attach to an 18 mm CrystalCap Copper or CrystalCap Copper Magnetic to create a 22mm length between the base of the cap and the beam.

ADJUSTABLE MOUNTED CRYOLOOP™

APPLICATION

- Cryocrystallography

FEATURES

- Adjustable loop orientation
- CryoLoops are pre-mounted
- Synthetic CryoLoop on adjustable stainless steel MicroTube
- MicroTube specially engineered with EasySnap notches
- Available in 20 micron diameter nylon
- Customize your CryoLoop orientation

DESCRIPTION

Similar to the Mounted CryoLoop™ in design and function, the Adjustable Mounted CryoLoop allows one to bend and orient the CryoLoop to multiple, unique positions previously unattainable with typical cryo setups. The Adjustable Mounted CryoLoop is a 20 micron diameter synthetic loop mounted inside a malleable stainless steel sleeve, which in turn, is mounted inside the EasySnap MicroTube™.

Using a specially designed L-shaped tool with a positioning notch, one can manipulate the angle and orientation of the CryoLoop by bending and adjusting the angle of the malleable stainless steel insert which holds the CryoLoop. The Adjustable Mounted CryoLoop may be positioned several times. Note: Repeated manipulation will fatigue the sleeve which can lead to failure of the sleeve. The Adjustable Mounted CryoLoop is designed to work with the CrystalCap System components.

The MicroTube is 24 mm in length and is specially engineered with EasySnap™ notches at the 10, 12, 14, 18, and 21 mm measures. To obtain the desired length of MicroTube, simply snap the MicroTube at the desired length and stake it to the CrystalCap Magnetic™ or CrystalCap Copper Magnetic™. These nylon loops show minimal diffraction, are thin for fast freezing, strong, and aerodynamic. Most data collection geometries prefer or require a 22 mm length between the base of the cap and the beam. For a 22 mm overall length using the CrystalCap, CrystalCap Magnetic and CrystalCap HT, snap the MicroTube at the second notch from the bottom. Snap the MicroTube at the fifth notch from the bottom (notch closest to the CryoLoop) and attach to an 18 mm CrystalCap Copper or CrystalCap Copper Magnetic to create a 22 mm length between the base of the cap and the beam.

MICROTUBE™

APPLICATION

- CryoLoop support for CrystalCap

FEATURES

- Laser-cut steel pin
- Use to mount CryoLoop to CrystalCap

DESCRIPTION

MicroTube
HR4-928

The MicroTube is the mount and support for the CryoLoop™ for crystallographers who prefer to mount their own CryoLoop. It fits into the pinhole opening on the CrystalCap™ or CrystalCap Copper™ (use 10 mm only) and is secured with epoxy or Super Glue. A CryoLoop is then secured into the opposite end of the MicroTube. The MicroTube is a laser-cut, 0.65 mm diameter stainless steel hollow tube. They are available in a variety of lengths to accommodate the wide range of geometries presented by various x-ray data collection systems. The 18 mm length MicroTube is the standard length used at most data collection facilities. Try a MicroTube FitKit pack to determine the best length for your application.

Determining MicroTube Length

Follow the instructions to determine which size works best for you. The following considerations have been taken in determining the length which is best suited for you:

Most XYZ goniometer heads have 5 mm of Z adjustment. The length of exposed loop stem on a Mounted CryoLoop is approximately 0.5 - 0.7 mm. When mounted properly, the length of exposed MicroTube set in a CrystalCap Copper is approximately 1.0 mm.

Recommendations:

Use 18 mm MicroTube with CrystalCap
Use 10 mm MicroTube with CrystalCap Copper 18 mm

CRYOLOOPS™ - 20 MICRON

APPLICATION

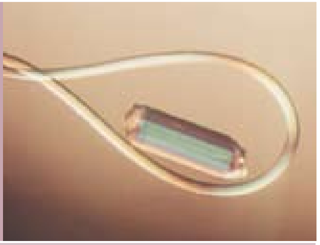
- Cryocrystallography

FEATURES

- Synthetic CryoLoop
- Complete range of loop diameters from 0.05 - 1.0 mm
- 20 micron diameter nylon

DESCRIPTION

CryoLoops in 20 micron diameter nylon. They are used to mount, freeze, and secure the crystal during cryocrystallographic procedures and x-ray data collection. These nylon CryoLoops show minimal diffraction, are thin for fast freezing, strong, and aerodynamic. Supplied as 10 loops per strip, 6 strips per package. Stake CryoLoops into MicroTubes™ using epoxy or Super Glue.



Crystal shown being collected using a Hampton Research CryoLoop.

CRYOLOOPS™ - 10 MICRON

APPLICATION

- Cryocrystallography

FEATURES

- Synthetic CryoLoop
- Complete range of loop diameters from 0.05 - 0.5 mm
- 10 micron diameter nylon

DESCRIPTION

CryoLoops are available in 10 and 20 micron diameters. They are used to mount, freeze, and secure the crystal during cryocrystallographic procedures and x-ray data collection. These synthetic CryoLoops show minimal diffraction, are thin for fast freezing, strong, and aerodynamic. Supplied as 10 loops per strip, 6 strips per package. Stake CryoLoops into MicroTubes™ using Super Glue (HR4-316). Please note that the 10 micron CryoLoops are very flexible due to their small diameter.

EPOXY

APPLICATIONS

- Sealing capillary tubes
- Securing MicroTubes into CrystalCaps
- Securing CryoLoops into MicroTubes

DESCRIPTION

5 minute, fast drying epoxy for sealing capillary tubes or securing MicroTubes into CrystalCaps or securing CryoLoops into MicroTubes. Sets in 5 minutes, can be handled in 15 minutes. Full bond strength in 1 hour. Requires no heat.

DEVCON

CRYOTONG™ - STANDARD

APPLICATION

- Crystal transfer under cryo temperature

FEATURES

- Artery clamp style closure
- 30 seconds of cryo temperature
- 7 different sizes
- 110 mm length

DESCRIPTION

The CryoTong is a tool used to manually transfer a crystal mounted on a CrystalCap™ from liquid nitrogen to a magnetic base in a goniometer head positioned in a cryogenic stream, and then back to liquid nitrogen. The one-piece, compact CryoTong is available in two lengths. The standard CryoTong is approximately 110 mm in length from the edge of the tool head to the end of the handle. The artery clamp style maintains the CryoTong in the closed position until the clamp is squeezed, which opens the opposing heads. The heads are non-magnetic stainless steel. The handle is magnetic stainless steel. The inside of the head is machined to closely surround the CrystalCap with loop and crystal in place. A small retaining lip is machined into the lower portion of the head to prevent the CrystalCap from slipping out when the tool is in the closed position. The CryoTong can maintain the temperature of the crystal at -160°C for up to 30 seconds during room temperature crystal transfers. The CryoTong is available in seven different sizes to fit 10 to 24 mm pin heights. Each size is designed to fit any of the the CrystalCap systems. Choose the proper CryoTong size based upon the pin length required by the configuration of the x-ray data collection hardware used. The 18 mm CryoTong (HR4-637) is to be used with the CrystalCap HT systems and any CrystalCap configured to 18 mm.

Order Information

Cat. No.	Name	Description	Price
HR4-631	**CryoTong - 10 mm**	each	**$55.00**
HR4-633	**CryoTong - 12 mm**	each	**$55.00**
HR4-635	**CryoTong - 14 mm**	each	**$55.00**
HR4-667	**CryoTong - 16 mm***	each	**$55.00**
HR4-637	**CryoTong - 18 mm**	each	**$55.00**
HR4-639	**CryoTong - 21 mm**	each	**$55.00**
HR4-641	**CryoTong - 24 mm**	each	**$55.00**

***The 16 mm CryoTong only works with the CrystalCap Copper 16 mm and the CrystalCap Copper Magnetic 16 mm.**

CRYOTONG™ - LONG

APPLICATION

- Crystal transfer under cryo temperature

FEATURES

- Artery clamp style closure
- 30 seconds of cryo temperature
- 7 different sizes
- 180 mm length

DESCRIPTION

The CryoTong is a tool used to manually transfer a crystal mounted on a CrystalCap™ from liquid nitrogen to a magnetic base in a goniometer head positioned in a cryogenic stream, and then back to liquid nitrogen. The one-piece, compact CryoTong is available in two lengths. The long CryoTong is approximately 180 mm in overall length. The artery clamp style maintains the CryoTong in the closed position until the clamp is squeezed, which opens the opposing heads. The heads are non-magnetic stainless steel. The handle is magnetic stainless steel. The inside of the head is machined to closely surround the CrystalCap with loop and crystal in place. A small retaining lip is machined into the lower portion of the head to prevent the CrystalCap from slipping out when the tool is in the closed position. The CryoTong can maintain the temperature of the crystal at -160°C for up to 30 seconds during room temperature crystal transfers. The CryoTong is available in seven different sizes to fit 10 to 24 mm pin heights. Each size is designed to fit all CrystalCap systems. Choose the proper CryoTong size based upon the pin length required by the configuration of the x-ray data collection hardware used. The 18 mm CryoTong (HR5-112) is to be used with the CrystalCap HT and any other CrystalCap configured for 18 mm.

HR5-114 Long CryoTong 18 mm, 180° features the head in alignment with the handle of the CryoTong.

HR5-113 Long CryoTong 18 mm, 45° features the head at a 45° angle to the handle of the CryoTong.

CRYSTALWAND™ - STANDARD

APPLICATION

- CrystalCap & CrystalCap Copper handling tool

DESCRIPTION

The CrystalWand is a chrome-plated steel wand, 9.6 mm in diameter with a magnet molded inside one end. The magnet is designed to fit the CrystalCap and CrystalCap Copper. The Crystal Wand makes it easy to manipulate, seed, mount, store, and handle crystals with the CrystalCap system. The CrystalWand is available in two styles (no tab and with tab) and two lengths (standard 130 mm and long 205 mm overall length). The long CrystalWand has a plastic handle.

Note: CrystalWand is not to be used with the CrystalCap Magnetic or CrystalCap Copper Magnetic or CrystalCap HT. Use the CrystalWand Magnetic for these products.

CrystalWand With Tab

CRYSTALWAND™ MAGNETIC

APPLICATION

- CrystalCap Magnetic & CrystalCap Copper Magnetic handling tool

DESCRIPTION

The CrystalWand Magnetic is designed to be used exclusively with the CrystalCap Magnetic, CrystalCap Copper Magnetic, and CrystalCap HT systems during transfer of the caps from the vial to the goniometer head and from the goniometer to the vial. The 6 1/2” (165 mm) long chrome plated steel wand features a plastic housing enclosing a spring tensioned plunger that when depressed, moves a non-magnetic steel platform away from the magnet housed in the end of the wand. This causes the steel CrystalCap to detach from the wand and be placed readily into the vial or the CryoTong™. When the platform is retracted, the wand securely holds the steel CrystalCap Magnetic. The CrystalWand Magnetic 45° (McMiken Tool) offers the same functionality but is bent at a 45° angle at approximately 2.5 cm from the magnet end.

Order Information

Cat. No.	Name	Description	Price
HR4-729	**CrystalWand Magnetic, Straight**	each	**$61.00**
HR4-315	**CrystalWand Magnetic, 45° (McMiken Tool)**	each	**$56.00**

VIAL CLAMP™ - STRAIGHT

APPLICATION

- Vial support and manipulation

FEATURES

- Straight end tip
- Hemostat style closure

DESCRIPTION

The Vial Clamp - Straight is a chrome plated, hemostat style tool. It has a tip shaped to hold the storage vial of all the CrystalCap™ systems straight when the clamp is closed. The clamp can be locked using the hemostat style closure. This clamp makes it easy to dip the storage vial into liquid nitrogen for crystal storage. The complete length of the clamp is straight, with an overall length of 195 mm. When the vial is placed in the clamp, the length of it is positioned perpendicular, 90° to the length of the clamp.

Order Information

Cat. No.	Name	Description	Price
HR4-670	Vial Clamp - Straight	each	$49.00

VIAL CLAMP™ - CURVED

APPLICATION

- Vial support and manipulation

FEATURES

- Curved end tip
- Hemostat style closure

DESCRIPTION

The Vial Clamp - Curved is a chrome plated, hemostat style tool. It has a tip shaped to hold the storage vial of all the CrystalCap systems at an angle when the clamp is closed. The clamp can be locked using the hemostat style closure. The end of the clamp, where the vial is held, is curved at either a 45°/135° or 110°/ 70° angle. When the vial is placed in the clamp, the length of it is positioned to the clamp at either of those same angles. The overall length of the clamp is 195 mm.

Order Information

Cat. No.	Name	Description	Price
HR4-671	Vial Clamp - Curved 45°/135°	each	$49.00
HR4-672	Vial Clamp - Curved 110°/70°	each	$75.00

TUBE CLAMP™

APPLICATION

- 15 ml vial support & manipulation

FEATURES

- Curved end tip
- Hemostat style closure

DESCRIPTION

The 7 1/2” (190 mm) long, 15 ml Tube Clamp is useful for holding and manipulating 15 ml screw top centrifuge tubes during cryocrystallographic procedures involving liquid propane and liquid nitrogen. The jaws of the clamp are designed to fit the outside diameter (16 mm) of most 15 ml screw top centrifuge tubes. When the vial is placed in the clamp, the length of it is positioned to the clamp at either a 45° or 135° angle, depending upon how one holds the clamp.

Order Information

Cat. No.	Name	Description	Price
HR4-727	Tube Clamp	each	$61.00

CRYSTALCAP™ HOLDER

APPLICATION

- CrystalCap support inside stainless steel dewars

FEATURES

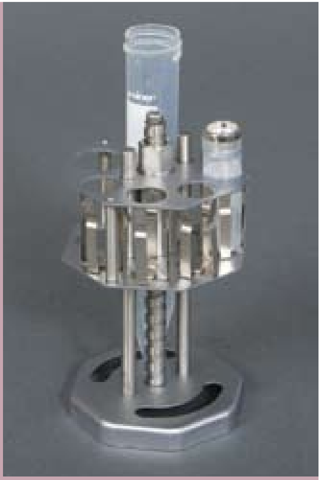
- Adjustable height
- Supports up to 8 CrystalCaps
- 15 ml vial position for liquid propane
- 500 and 1,000 ml versions

DESCRIPTION

CrystalCap Holders are convenient stands for holding all CrystalCap systems in liquid nitrogen dewars during crystal cryogenic procedures. Available in two sizes. Both holders feature spring-clips to secure the CrystalCap Vials in the holder. Both stands have 3" of adjustable Z (height) which allows one to raise or lower the CrystalCaps to the appropriate height, depending upon the liquid nitrogen level in the dewar. Each holder is supplied with a socket driver for height adjustment.

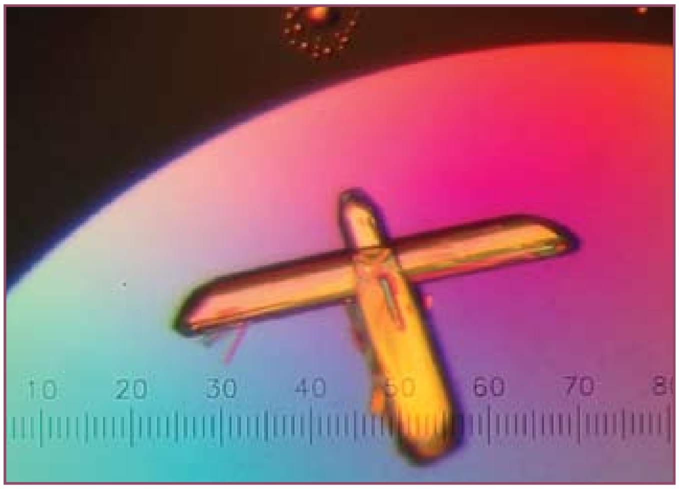
500 ml version holds five CrystalCaps, two 15 ml vials (for liquid propane procedures) and fits into the 500 ml dewar. 1,000 ml version holds eight CrystalCaps, two 15 ml vials (for liquid propane procedures) and fits into the 1,000 ml dewar.

The HR4-705 is approximately 98 mm wide (measured at corners of hexagon)/92 mm wide (measured at flats of hexagon) by approximately 120 mm tall.



Order Information

Cat. No.	Name	Description	Price
HR4-707	CrystalCap Holder - 500 ml	each	$109.00
HR4-705	CrystalCap Holder - 1,000 ml	each	$109.00
HR4-706	Replacement Height Adjustment Tool	each	$15.00



Protein crystals.

CRYOCANE

APPLICATION

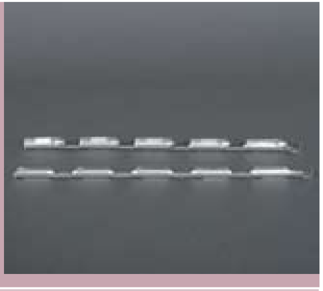
- Organized storage of CrystalCaps

FEATURES

- 2 styles: 5 or 6 vial holding canes
- Made of aluminum
- Compatible with the CrystalCap systems

DESCRIPTION

Aluminum CryoCanes firmly hold CrystalCap™, CrystalCap Copper, CrystalCap Magnetic, and CrystalCap Copper Magnetic vials for storage in dewar-type, liquid nitrogen freezers. The 5 vial CryoCane offers base tabs for proper CrystalCap seating whereas the 6 vial CryoCane offers free alignment. Length of 5 vial version: 11 5/16" (28.7 cm). Length of 6 vial version: 11 13/16" (30 cm).



Order Information

Cat. No.	Name	Description	Price
HR4-709	**CryoCane 5 Vial Holder**	12 pack	**$24.00**
HR4-711	**CryoCane 6 Vial Holder**	12 pack	**$26.00**

CRYOCANE COLOR CODERS

APPLICATION

- Identify & organize CryoCanes

FEATURES

- Compatible with the CrystalCap systems
- Made of aluminum
- 5 colors to choose from

DESCRIPTION

Colored aluminum tabs slip into the ends of CryoCane holders to identify a set of vials, a researcher's work, or sample. Flat writing surface allows for additional identification. Available in five different colors.

Order Information

Cat. No.	Name	Description	Price
HR4-722	**CryoCane Color Coder - Sampler**	60 pack (12 of each color)	**$50.00**

CRYOSLEEVE

APPLICATION

- Use with CryoCanes

FEATURES

- Will not become brittle
- Made of polyvinyl
- Compatible with the CrystalCap systems

DESCRIPTION

Clear polyvinyl sleeve encloses CrystalCap on a CryoCane Holder for extra security during handling, transport, and storage. Will not become brittle during freezing or thawing. Unlike cardboard, will not shred, tear, or fall to pieces after repeated use. 10 13/16" length (27.5 cm).

HR4-708	**CryoSleeve**	12 pack	**$18.00**

DEWARS

STAINLESS STEEL DEWAR

APPLICATION

- Cryogenic procedures

FEATURES

- Made of 304 stainless steel
- Available in 500 ml and 1,000 ml sizes
- Compatible with CrystalCap Holders

DESCRIPTION

Unbreakable, 304 stainless steel construction dewars for cryocrystallography. Convenient for the flash freezing of crystals, these dewars store and transport low temperature liquid gases such as liquid nitrogen and can withstand temperatures from -196°C to 204°C. The dewars are impervious to vibrations. In comparison tests, these stainless steel dewars outperform common metal dewars by 20% and perform comparable to glass modules. Only the 1,000 ml dewar comes with a stainless steel carrying handle. Each dewar is supplied with a stainless steel cover. Covers are also available separately.

500 ml stainless steel dewar flask (2.5"ID, 3.4"OD, 7.0" depth, 8" height) - right in the picture. 1,000 ml stainless steel dewar flask (3.9"ID, 4.8" OD, 6.2" depth, 6.9" height) - left in the picture.

GLASS DEWAR

APPLICATION

- Cryogenic procedures

FEATURES

- Low form, shallow 600 ml base
- Low sidewall for easier access
- Manufactured for service of liquid nitrogen

DESCRIPTION

Low form, glass, shallow dewar for use with materials ranging from dry ice/acetone to liquid nitrogen. This 600 ml full base hemispherical bottom dewar is a low form with full aluminum protective coating. Low sidewall allows easier access to cryogen.

Dimensions: ID 140 mm, inside depth 65 mm, OD 165 mm, total height 95 mm. Accepts 500 ml flask. Manufactured by Pope Scientific.

For optimum results, temper the Dewar per instructions included with each dewar. Refer to The Care and Use of Pope Dewar Flasks.

Order Information

Cat. No.	Name	Description	Price
HR5-102	**Low Form Dewar**	each	**$268.00**

FOAM DEWAR

APPLICATION

- Cryocrystallography

FEATURES

- Each dewar is supplied with a lid
- Proprietary foam construction
- Standard (800 ml) and Tall (2 liter)

DESCRIPTION

Spearlab Cryogenic Foam Dewar (800 ml) - Standard: The standard foam dewar shape is circular, with a protruding handle, so that it resembles a large teardrop. Each dewar is supplied with a matching foam lid to insulate the contents from ambient air. Dimensions of the cylindrical cavity in this vessel are 5.8" in diameter by 2.8" deep, so that it easily holds 800 ml of liquid nitrogen.

Spearlab Cryogenic Foam Dewar (2 liter) - Tall: The tall foam dewar shape is a tapered octagon on the outside with a cylindrical interior. The tapered octagon features a wide, stable base. Each dewar is supplied with a matching foam lid to insulate the contents from ambient air. Dimensions of the cylindrical cavity in this vessel are 3.5" in diameter by 12.5" deep, so that it holds approximately 1,970 ml of liquid nitrogen. The outside dimensions of the tall dewar are 15.25" tall with a 6.25" wide top and a 7.75" wide base (measured on the flats of the octagon). The cover is 6.5" in diameter and 0.5" thick.

The patent pending design of the Spearlab Cryogenic Foam Dewar makes it easy to handle and safer to use than a traditional low profile glass dewar. Also, because of its lower thermal mass, a foam vessel will cause less boil off when it is filled with liquid nitrogen. Additionally, the dewar will accumulate less frost during regular use. The end result is that less liquid nitrogen is consumed.

HAMPTON
RESEARCH

APPLICATIONS

- X-ray data collection
- Liquid-liquid diffusion crystallization
- Gel acupuncture crystallization

FEATURES

- 3 glass types
- Thin walled

DESCRIPTION

Crystal Clear Glass and Quartz capillaries that are extremely thin walled (approximately 10 microns wall thickness). The length of the capillary has a well defined diameter, with one end having a funnel shape and the other end closed. Capillaries have a wall thickness of 0.01 mm and an overall length of 80 mm. Capillaries are available in a wide range of outside diameters from 0.1 to 2.0 mm (5.0 mm for quartz only). The capillaries are designed to mount, hold, and store small molecule and biological macromolecular crystals for x-ray data collection. Capillaries can also be used for crystal density measurements and crystal growth experiments. The capillaries can be sealed tightly against moisture and gases using wax, epoxy, or other sealing materials.

In determining what glass or quartz capillary is right for you, please refer to the "Linear Absorption Coefficient μ cm^{-1}" table. This table indicates the amount of radiation that is absorbed by the capillary during x-ray data collection.

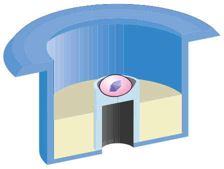
Linear Absorption Coefficient μ cm^{-1}

Glass Type	μ CuK L Radiation	μ MoK L Radiation	Softening Temp.
10	126.0	14.7	708°C
50	71.0	7.35	815°C
Quartz	75.8	8.2	1,730°C

HOW TO: MOUNTING CRYSTALS USING CAPILLARIES

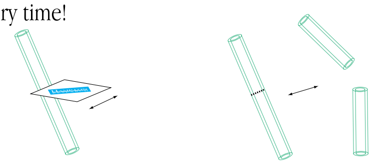
Step 1 - Choosing a crystal

Locate the crystal of interest to be mounted in the capillary. Measure the size of crystal. This will determine what diameter capillary to use.



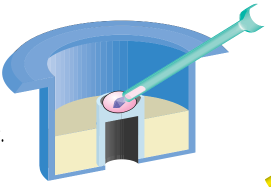
Step 2 - Cutting the capillary

Select the size of capillary. Score the capillary near the sealed end using the Capillary Cutting Stone. Snap the capillary at the score mark. A clean cut every time!



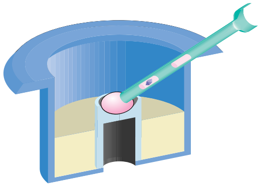
Step 3 - Make a slug

On the funnel end of the capillary attach a flexible adaptor to use a syringe or pipet. Suck up a small amount of mother liquor. This will be your mother liquor slug to prevent the crystal from drying out during data collection.



Step 4 - Obtaining the crystal

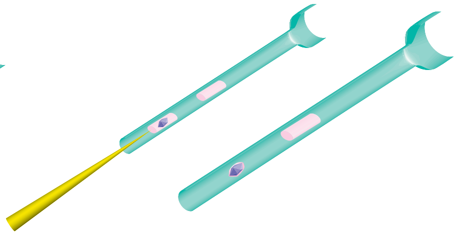
Remove the capillary from the drop and place an air gap into the capillary. This will separate the slug from the crystal.



Place the capillary back into the drop and suck up the crystal. Try not to obtain too much mother liquor while picking up the crystal.

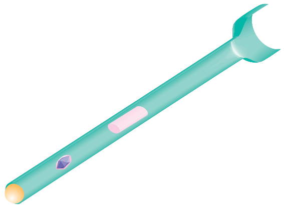
Step 5 - Removing excess mother liquor

Using either the Paper Wicks or the MicroWick, remove any excess mother liquor from around the crystal. There should only be a minimal amount of mother liquor surrounding the crystal. This will help reduce background scattering and reduce crystal slippage.



Step 6 - Sealing one end

Using either Beeswax or Capillary Wax, seal off the open end of the capillary. Do not overheat the wax for this will move or even damage the crystal.



Step 7 - Sealing the other end

Trim off the funnel part of the capillary using the Capillary Cutting Stone as described in Step 2.

Finally, seal off the open end of the capillary as described in Step 6.

Using Mounting Clay or an Adjustable Crystal Mount, and a Brass Pin, place the capillary containing your crystal onto the goniometer head. You are now ready to collect data.

0.9 mm
Quartz Capillary

CAPILLARIES

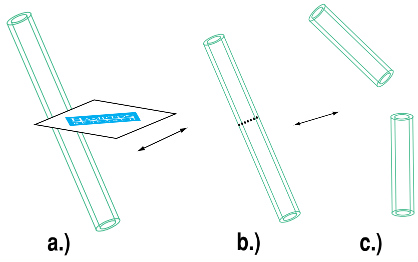
CAPILLARY CUTTING STONE™

APPLICATION

- The easiest way to cut capillaries

FEATURES

- Score and snap



DESCRIPTION

These small (25 mm x 25 mm x 0.65 mm) cutting stones are used to make clean cuts of glass and quartz capillaries. Use the edge of the stone to etch the capillary then gently snap the capillary in two. This is useful for cutting the tips off closed capillaries used for mounting single crystals for x-ray diffraction analysis or for cutting capillaries to the desired length.

HR4-334	**Capillary Cutting Stone**	each	**$15.00**

GLASS FIBERS

APPLICATION

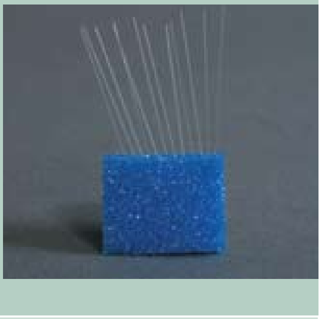
- Crystal mounts for small molecules

FEATURES

- Two sizes: 0.1 - 0.3 mm & 0.3 - 0.5 mm
- Length: 40 mm

DESCRIPTION

40 mm length glass fibers for small molecule crystal mounts. Available in 0.1 - 0.3 mm and 0.3 - 0.5 mm diameter glass. Simple to use. Glue the glass fiber to a brass specimen pin. Adhesives for attaching glass fibers to the brass pins can be found in Capillary Essentials. Add a very small amount of the adhesive of choice to the tip of the glass fiber. Carefully bring the fiber into solid contact with the crystal face and leave in this orientation long enough for the glue to set firmly. Position onto goniometer head and collect data.



Order Information

Cat. No.	Name	Description	Price
HR8-030	**Glass Fiber**	0.1 - 0.3 mm diameter - 25 pack	**$15.00**
HR8-032	**Glass Fiber**	0.3 - 0.5 mm diameter - 25 pack	**$15.00**

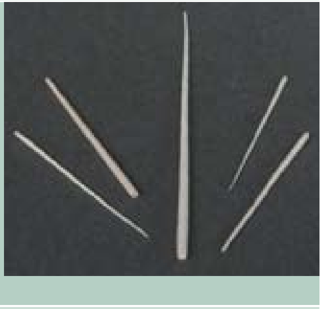
PAPER WICKS™

APPLICATIONS

- Remove excess mother liquor from inside capillaries and CryoLoops
- Remove stray drops

DESCRIPTION

Sterile Paper Wicks are available in a variety of sizes. Smaller diameter wicks (in 25 mm & 55 mm lengths) are useful for wicking away mother liquor from within capillary tubes and CryoLoops while mounting crystals. Larger diameter wicks (in 25 mm & 55 mm lengths) are useful for removing stray/excess solvent from crystallization setups.



Order Information

Cat. No.	Name	Description	Price
HR4-110	**Assorted Paper Wicks - 25 mm**	XXX Fine - X Fine - 200 wicks	**$15.00**
HR4-122	**Paper Wicks - 25 mm**	XXX Fine - 200 wicks	**$15.00**
HR4-112	**Paper Wicks - 25 mm**	XX Fine - 200 wicks	**$15.00**
HR4-114	**Paper Wicks - 25 mm**	X Fine - 200 wicks	**$15.00**
HR4-116	**Paper Wicks - 25 mm**	Fine - 200 wicks	**$15.00**
HR4-211	**Paper Wicks - 55 mm**	X Fine Long - 100 wicks	**$15.00**
HR4-213	**Paper Wicks - 55 mm**	Medium Long - 100 wicks	**$15.00**

MICROWICK™

APPLICATION

- Remove excess mother liquor from inside capillaries

DESCRIPTION

MicroWick is useful for removing mother liquor from inside capillaries during crystal mounting. MicroWick is a non-metallic syringe needle used for filling and removing liquid from capillaries and micropipettes. MicroWick features a 70 mm tip, 0.164 mm OD, 0.1 mm ID (34 gauge) tip which will fit into most capillaries and micropipettes with an internal diameter of 0.2 mm or larger. The MicroWick needle is constructed from a combination of plastic and fused silica - no metal components are used. The MicroWick tip elasticity is sturdy and flexible though not unbreakable (much more flexible than glass!). Moderate bending will not block or damage the needle. The MicroWick luer fitting allows easy coupling to syringes and syringe filters. Each MicroWick contains one needle and one 1 ml syringe. Crystallization and capillary accessories sold separately.

Order Information

Cat. No.	Name	Description	Price
HR4-330	**MicroWick**	each	**$31.00**

CAPILLARY SEALANTS

EPOXY

APPLICATIONS

- Sealing capillaries
- Staking MicroTubes into CrystalCaps
- Mount crystals to glass fibers

DESCRIPTION

5 minute, fast drying epoxy for sealing capillary tubes or staking MicroTubes™ into CrystalCaps™. Sets in 5 minutes, can be handled in 15 minutes. Full bond strength in 1 hour. Requires no heat!

Order Information

Cat. No.	Name	Description	Price
HR4-318	**Epoxy Dual Syringe**	25 ml tube	**$10.00**
HR4-346	**Epoxy & Hardener**	35 g tube (2 pack)	**$9.00**

DUCO® CEMENT

APPLICATIONS

- Sealing capillaries
- Mount crystals to glass fibers

DESCRIPTION

Old school cement for sealing glass capillaries when mounting crystals. Requires no heat!

Order Information

Cat. No.	Name	Description	Price
HR4-320	**Duco Cement**	29 ml tube	**$7.00**

SUPER GLUE

APPLICATIONS

- Staking glass fibers to brass specimen pins
- Staking CryoLoops to MicroTubes

DESCRIPTION

Super glue for staking glass fibers to brass specimen pins, crystal mounting, and sticking fingers together.

Order Information

Cat. No.	Name	Description	Price
HR4-316	**Super Glue**	2 g tube	**$5.00**

BEESWAX™

APPLICATIONS

- Sealing capillaries
- Keep bees busy

DESCRIPTION

Pure, natural, and soft Beeswax™ - golden in color. Beeswax has a melting point of 63°C/146°F. Beeswax comes in seven easy to peel wrapped sticks making it very convenient to handle. Very useful for sealing the ends of capillary tubes when mounting crystals.

Order Information

Cat. No.	Name	Description	Price
HR4-312	Beeswax Stick	7 sticks	$30.00

CAPILLARY WAX™

APPLICATION

- Sealing capillaries

DESCRIPTION

A hard, brittle wax orange in color useful for sealing crystals in glass capillaries. Non-malleable. Melt with soldering iron or other heat device and apply to glass or quartz capillaries. When applied properly, Capillary Wax will provide an airtight seal. Also referred to as “sticky wax”.

Order Information

Cat. No.	Name	Description	Price
HR4-328	Capillary Wax	40 g pack (approximate)	$25.00

WAX PEN™

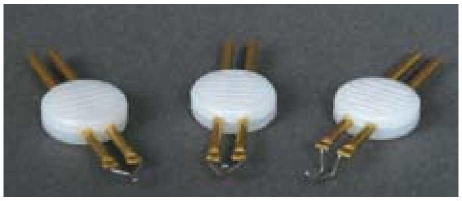
APPLICATION

- Sealing capillaries

DESCRIPTION

The Wax Pen™ is a hot pen, powered by two AA batteries (supplied). Pressing a switch heats the tips of the pen to a temperature that melts Beeswax and Capillary Wax which are used for sealing capillaries.

Replacement tips are available in a pack of three different shaped tips (straight loop, straight flat, and curved loop).



Order Information

Cat. No.	Name	Description	Price
HR4-342	Wax Pen	each	$50.00
HR4-344	Wax Pen Replacement Tips	3 tip pack	$21.00

RED STICKY WAX

APPLICATIONS

- Stabilizing the capillary on the goniometer head or brass specimen pin
- Prop open lids of Linbro® plates
- Make bendable buddies

DESCRIPTION

Soft, malleable, cylindrical wax ropes with similar properties as mounting clay. Uses include propping open the lids of Linbro® crystallization plates, supporting small items, and stabilizing capillaries.

Order Information

Cat. No.	Name	Description	Price
HR4-310	**Red Sticky Wax**	44 wax ropes	**$20.00**

FOUR COLOR MOUNTING CLAY

APPLICATION

- Stabilizing the capillary on the goniometer head or brass specimen pin

FEATURES

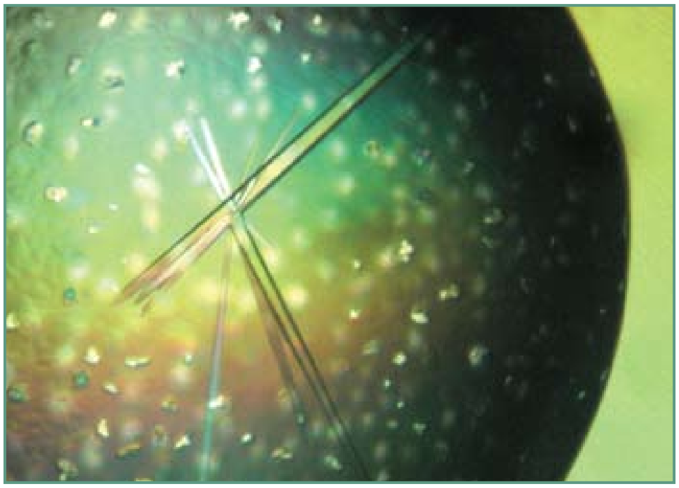
- Color code capillary mounts

DESCRIPTION

Adhesive, malleable, non-hardening clays have many uses in the crystallization lab. Useful for holding capillaries during crystal mounting as well as, stabilizing the capillary in the goniometer head. Useful for propping open the lids of crystallization plates. Great for color coding experiments, capillaries, and Linbro® crystallization plates. Each 4 oz brick of clay is individually wrapped.

Order Information

Cat. No.	Name	Description	Price
HR4-326	**Four Color Mounting Clay**	16 oz pack (4 oz each blue/yellow/red/green)	**$12.00**



Vvn protein with DNA "diamond clock".

Lucy Doudeva, Hanna Yuan's lab, Academia Sinica, Taiwan.

ADJUSTABLE CRYSTAL MOUNT™

APPLICATION

- Adjustable, magnetic crystal mounting with capillaries or fibers

FEATURES

- Adjustable Z
- Magnetic mount
- Fits XYZ Goniometer Heads with Z Platform or magnetic base
- Fast, easy convenient crystal positioning and retrieval

DESCRIPTION

The Adjustable Crystal Mount is a magnetic piece (approximately 12 mm in height, 9.8 mm in diameter) designed to position a brass specimen pin (below) and either a capillary or glass fiber onto a goniometer head for x-ray data collection. The Adjustable Crystal Mount is engineered to fit onto the Z Platform or magnetic base within a goniometer head. The recessed bottom properly positions the Crystal Mount over the center of the goniometer head and prevents the mount from sliding across the goniometer head during data collection. The bottom of the Crystal Mount is flat and closed to prevent the brass specimen pin from protruding through the bottom of the Mount. The magnetic design allows for quick, convenient, and rapid placement and retrieval of the Crystal Mount. Finally, the Crystal Mount is designed with a single allen screw which allows the Z-translation of the brass specimen pin to be adjusted (up and down) and then secured in position by tightening the allen screw using the Goniometer Head Key.

Order Information

Cat. No.	Name	Description	Price
HR8-028	**Adjustable Crystal Mount**	5 pack	**$58.00**

BRASS SPECIMEN PIN™

APPLICATIONS

- Capillary and glass fiber mounts
- Small molecules and macromolecules

FEATURES

- Available with or without a platform

DESCRIPTION

3 mm brass specimen pins with platform for capillary mounting using Four Color Mounting Clay™ or Red Sticky Wax™. The platform has a diameter of 9 mm which adds for extra stability in maintaining a straight capillary for x-ray data collection. Conforms to IUCr standards.

Order Information

Cat. No.	Name	Description	Price
HR4-661	**Brass Specimen Pin**	25 pack	**$32.00**
HR4-663	**Brass Specimen Pin with Platform**	25 pack	**$46.00**

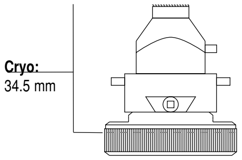
XYZ HEATED GONIOMETER HEADS

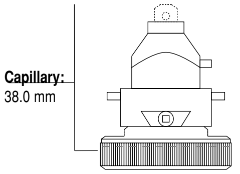
XYZ HEATED GONIOMETER HEAD™

FEATURES

- Heated goniometer head
- Prevent icing on goniometer head & pin
- Head height: Cryo: 34.5 mm
  Capillary: 38.0 mm
- Adjustments: X & Y: ± 2.5 mm
  Z: ± 5 mm



Goniometer Head with Cryo Mount



Goniometer Head with Capillary Mount

DESCRIPTION

34.5 mm height with Z Platform™ magnetic base for cryocrystallography. 38.0 mm height with Z Capillary™ for capillary mounts (measurements from the top of a lowered Z Platform/Z Capillary to the point where the base mount of the goniometer head attaches to the goniometer). ± 2.5 mm X and Y adjustments, 5 mm Z adjustment. Ceramic heating element in base of goniometer head maintains the head and mounting pin at a temperature that prevents icing. Temperature controller requires 120/230 volt AC. Head is equipped with an ACA/IUCr standard thread and support.

Each XYZ Heated Goniometer Head includes a heated goniometer head, Z capillary mount, Z Platform 9,000 gauss magnetic base, adjustment key, and storage case. Temperature controller, connection cable, and transformer (120v USA or 230v International) are required and sold separately. Crystallization and goniometer head accessories available separately.

Base thread is M30, 1 mm/thread.

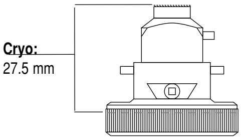
Order Information

Cat. No.	Name	Description	Price
HR4-767	**XYZ Heated Goniometer Head**	each	**$685.00**

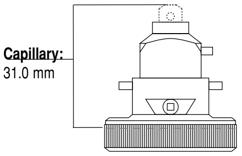
XYZ SHORT HEATED GONIOMETER HEAD™

FEATURES

- Heated goniometer head
- Prevent icing on goniometer head & pin
- Head height: Cryo: 27.5 mm
  Capillary: 31.0 mm
- Adjustments: X & Y: ± 2.5 mm
  Z: ± 5 mm



XYZ Short Heated Goniometer Head with Cryo Mount



XYZ Short Heated Goniometer Head with Capillary Mount

DESCRIPTION

27.5 mm height with Z Platform™ magnetic base for cryocrystallography. 31.0 mm height with Z Capillary™ for capillary mounts (measurements from the top of a lowered Z Platform/Z Capillary to the point where the base mount of the goniometer head attaches to the goniometer). ± 2.5 mm X and Y adjustments, 5 mm Z adjustment. Ceramic heating element in base of goniometer head maintains the head and mounting pin at a temperature that prevents icing. Temperature controller requires 120/230 volt AC. Head is equipped with an ACA/IUCr standard thread and support.

Each XYZ Short Heated Goniometer Head includes a short heated goniometer head, Z capillary mount, Z Platform 9,000 gauss magnetic base, adjustment key, and storage case. Temperature controller, connection cable, and transformer (120v USA or 230v International) are required and sold separately. Crystallization and goniometer head accessories available separately.

Base thread is M30, 1 mm/thread.

Order Information

Cat. No.	Name	Description	Price
HR4-765	**XYZ Short Heated Goniometer Head**	each	**$685.00**

TEMPERATURE CONTROLLER

FEATURES

- Temperature controller for all XYZ heated heads

DESCRIPTION

Temperature Controller for the XYZ Heated™ and XYZ Short Heated™ goniometer heads. Includes connection cable.

Order Information

Cat. No.	Name	Description	Price
HR4-775	Temperature Controller	each	$98.00

TRANSFORMER

FEATURES

- Power supply for all XYZ heated heads

DESCRIPTION

Transformer (power supply) for the XYZ Heated and XYZ Short Heated goniometer heads. Available for both 120v and 230v applications.

Order Information

Cat. No.	Name	Description	Price
HR4-669	24V Transformer - 120V	each	$41.00
HR4-755	24V Transformer - 230V	each	$45.00

CONNECTION CABLE

FEATURES

- Connection cable for all XYZ heated heads

DESCRIPTION

Replacement connection cable for the XYZ Heated and XYZ Short Heated goniometer heads. Connects goniometer head to temperature controller.

Order Information

Cat. No.	Name	Description	Price
HR4-657	Connection Cable	each	$11.00

TEMPERATURE CONTROLLER FUSE

FEATURES

- Fuse for temperature controllers

DESCRIPTION

Replacement fuse for the temperature controller.

Order Information

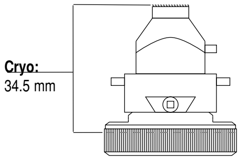
Cat. No.	Name	Description	Price
HR4-777	Temperature Controller Fuse	3 pack	$8.00

XYZ STANDARD GONIOMETER HEADS

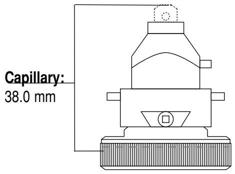
XYZ STANDARD GONIOMETER HEAD™

FEATURES

- Head height: Cryo: 34.5 mm
  Capillary: 38.0 mm
- Adjustments: X & Y: ± 2.5 mm
  Z: ± 5 mm



Goniometer Head with Cryo Mount



Goniometer Head with Capillary Mount

DESCRIPTION

34.5 mm height with Z Platform™ magnetic base for cryocrystallography. 38.0 mm height with Z Capillary™ for capillary mounts (measurements from the top of a lowered Z Platform/Z Capillary to the point where the base mount of the goniometer head attaches to the goniometer). ± 2.5 mm X and Y adjustments, ±5 mm Z adjustment. Includes XYZ Goniometer Head, Z Capillary Mount, Z Platform 9,000 gauss magnetic base, adjustment key, and storage case. Head is equipped with an ACA/IUCr standard thread and support.

Base thread is M30, 1 mm/thread.

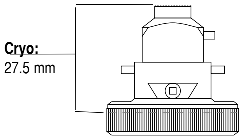
Order Information

Cat. No.	Name	Description	Price
HR4-647	XYZ Standard Goniometer Head	each	$590.00

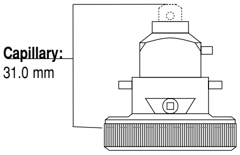
XYZ SHORT STANDARD GONIOMETER HEAD™

FEATURES

- Head height: Cryo: 27.5 mm
  Capillary: 31.0 mm
- Adjustments: X & Y: ± 2.5 mm
  Z: ± 5 mm



XYZ Short Goniometer Head with Cryo Mount



XYZ Short Goniometer Head with Capillary Mount

DESCRIPTION

27.5 mm height with Z Platform™ magnetic base for cryocrystallography. 31.0 mm height with Z Capillary™ for capillary mounts (measurements from the top of a lowered Z Platform/Z Capillary to the point where the base mount of the goniometer head attaches to the goniometer) . ± 2.5 mm X and Y adjustments, ±5 mm Z adjustment. Includes XYZ Short Goniometer Head, Z Capillary mount, Z Platform 9,000 gauss magnetic base, medium (6,000 gauss) magnetic base, adjustment key, and storage case. Head is equipped with an ACA/IUCr standard thread and support.

Base thread is M30, 1 mm/thread.

Order Information

Cat. No.	Name	Description	Price
HR4-643	XYZ Short Standard Goniometer Head	each	$590.00

STORAGE CASE FOR GONIOMETER HEAD

FEATURES

- Plastic storage case for IUCr standard thread goniometer heads

DESCRIPTION

Black plastic base threads securely into clear plastic cover and is threaded to hold IUCr standard thread goniometer heads.

Base thread is M30, 1 mm/thread.

Order Information

Cat. No.	Name	Description	Price
HR4-753	**Storage Case for Goniometer Head**	each	$20.00

GONIOMETER HEAD KEY

FEATURES

- Works with all XYZ heads

DESCRIPTION

Goniometer head key for use with all XYZ goniometer heads. This key is included with the purchase of any goniometer head.

Order Information

Cat. No.	Name	Description	Price
HR4-659	**Goniometer Head Key**	each	$11.00

SET SCREWS

FEATURES

- Replacement set screws for all XYZ heads

DESCRIPTION

Replacement set screws are available for the X and Y translation (2 mm x 4 mm) and for Z translation collar (2 mm x 1 mm).

Order Information

Cat. No.	Name	Description	Price
HR6-100	**X & Y Translation Set Screw**	3 pack	$9.00
HR6-102	**Z Translation Collar Set Screw**	3 pack	$9.00

Z CAPILLARY™ SUPPORT

FEATURES

- Capillary pin support for all XYZ heads
- Supports brass specimen pins

DESCRIPTION

Replacement Z Capillary Support for all XYZ goniometer heads.

Order Information

Cat. No.	Name	Description	Price
HR4-769	**Z Capillary**	For all XYZ short heads - each	**$37.00**
HR4-771	**Z Capillary**	For all XYZ heads - each	**$37.00**

ADJUSTABLE CRYSTAL MOUNT

APPLICATION

- Adjustable, magnetic crystal mounting with capillaries or fibers

FEATURES

- Adjustable Z
- Magnetic mount
- Fits XYZ Goniometer Heads with Z Platform or magnetic base
- Fast, easy, and convenient crystal positioning and retrieval

DESCRIPTION

The Adjustable Crystal Mount is a magnetic piece (approximately 12 mm in height, 9.8 mm in diameter) designed to position a brass specimen pin (below) and either a capillary or glass fiber onto a goniometer head for x-ray data collection. The Adjustable Crystal Mount is engineered to fit onto the Z Platform or magnetic base within a goniometer head. The recessed bottom properly positions the crystal mount over the center of the goniometer head and prevents the mount from sliding across the goniometer head during data collection. The bottom of the crystal mount is flat and closed to prevent the brass specimen pin from protruding through the bottom of the mount. The magnetic design allows for quick, convenient, and rapid placement and retrieval of the crystal mount. Finally, the crystal mount is designed with a single allen screw which allows the Z-translation of the brass specimen pin to be adjusted (up and down) and then secured in position by tightening the allen screw using the Goniometer Head Key.

MAGNETIC BASE

FEATURES

- Available in 3 strengths
- Magnetic support for CrystalCap

DESCRIPTION

The CrystalCap Magnetic Base (9.3 mm diameter support) is a machined brass piece fitted with a magnet. The base fits into the goniometer head, providing a secure base for the CrystalCap Magnetic System™. Fits most goniometer heads. The CrystalCap Magnetic Base is available in three strengths: strong, medium, and light. The stem of the magnet is 3 mm in diameter. The length of the stem is 5 mm. The thickness of the platform is 3.6 mm.

Order Information

Cat. No.	Name	Description	Price
HR4-943	**Magnetic Base - Strong**	9,000 gauss - each	**$35.00**
HR4-627	**Magnetic Base - Medium**	6,000 gauss - each	**$35.00**
HR4-629	**Magnetic Base - Light**	4,000 gauss - each	**$35.00**

MAGNETIC BASE SUPPORT Z PLATFORM™ - LIGHT

FEATURES

- Light strength (6,000 gauss) magnetic support for all XYZ heads
- Magnetic support for CrystalCap

DESCRIPTION

Z Platform™ with 6,000 gauss magnet for all XYZ goniometer heads. Less pull and reduced "snapping" than Z Platform with 9,000 gauss magnet.

Order Information

Cat. No.	Name	Description	Price
HR4-651	**Z Platform - Light**	For all XYZ short heads - each	**$37.00**
HR4-653	**Z Platform - Light**	For all XYZ heads - each	**$37.00**

MAGNETIC BASE SUPPORT Z PLATFORM™ - STRONG

FEATURES

- Strong strength (9,000 gauss) magnetic support for all XYZ heads
- Magnetic support for CrystalCap

DESCRIPTION

Z Platform™ with 9,000 gauss magnet for all XYZ goniometer heads. Same Z Platform that is included with the purchase of any goniometer head.

Order Information

Cat. No.	Name	Description	Price
HR4-761	**Z Platform - Strong**	For all XYZ short heads - each	**$35.00**
HR4-763	**Z Platform - Strong**	For all XYZ heads - each	**$35.00**

XENON CHAMBER™

APPLICATION

- Produce xenon derivatives of biological macromolecular crystals

FEATURES

- Operation pressure range of 0 to 600 psi
- Small pressure chamber for minimum xenon gas consumption
- Pressure regulated safety valve
- Safety lock prevents opening of pressurized chamber
- Safety shield between pressure chamber and user
- Quick release connectors between xenon gas supply and pressure chamber
- High quality xenon pressure regulator with needle valve for fine control
- Unique track design allows rapid crystal transfer from xenon to dewar for freezing
- Mini-Vial/Wick system prevents crystal dehydration
- CrystalCap compatible

DESCRIPTION

The Xenon Chamber is a pressure chamber designed to produce xenon derivatives of biological macromolecular crystals.

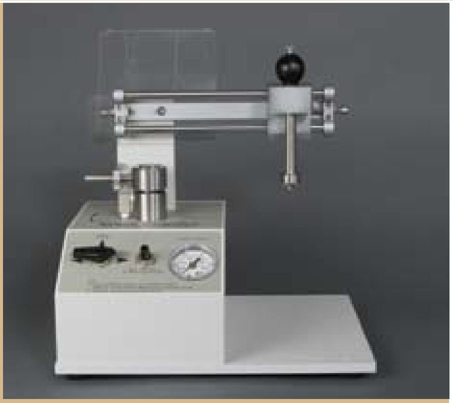
Aside from the preparation of a pure sample and subsequent crystallization, an often rate-limiting step in the determination of biological macromolecular structures by x-ray diffraction analysis is the formation of isomorphous heavy atom derivatives. Typically, isomorphous derivatives are formed by diffusing heavy atoms such as lead or mercury based compounds into the crystal with the anticipation that the heavy atom molecules will bind in an ordered fashion to each biological macromolecule. In order to obtain two or more successful isomorphous derivatives, a researcher may need to evaluate close to 100 different heavy atom compounds by manually transferring a number of crystals to different mother liquors each containing a different heavy atom compound.

Enter Xenon

Xenon is a noble gas which binds to specific sites in a biological macromolecule. There are numerous examples demonstrating that xenon-macromolecule complexes can serve as heavy atom derivatives.[1-8] The xenon-macromolecule complex is obtained by placing the macromolecular crystal under a pressurized xenon atmosphere. A clear advantage in using xenon is that one can simply screen xenon by pressurizing a loop-mounted crystal rather than having to set up plates and having to transfer crystals from numerous drops.

Enter the Xenon Chamber

The Xenon Chamber is a simple, yet effective device designed to pressurize loop-mounted biological macromolecular crystals in the presence of xenon gas at room temperature. Crystals mounted in loops such as the CrystalCap system are placed into the Xenon Chamber. Once sealed, the chamber is pressurized with xenon gas so that the crystal and macromolecules are equilibrated in a vapor saturated xenon atmosphere. Following depressurization of the chamber, the loop-mounted crystal is simply lifted and slid along the Xenon Chamber track and quickly lowered into a dewar for freezing in liquid nitrogen or propane. The transfer from pressurized xenon to the freeze is accomplished in seconds.



Specifications

The Xenon Chamber measures 14 1/4" tall, 13 1/2" wide, and 10 1/4" deep. The pressure chamber measures 9.5 mm (diameter) by 29 mm (depth).

The Xenon Chamber has an operation pressure range of 0 to 600 psi (0 to 4.1 Mpa, 0 to 41 Bar).

The pressure regulator for the Xenon Chamber is designed to be used with inert gases such as xenon. The CGA number for the pressure regulator is 580. The pressure regulator has a hose length of 21" with a quick connector on the end to attach it to the Xenon Chamber.

Each Xenon Chamber comes complete with a CrystalCap Dewar Stand that fits the 1,000 ml Dewar Flask (HR4-699) and a pack of five Mini-Vials with Wicks. The Xenon Chamber Pressure Regulator is sold separately. Additional Mini-Vials with Wick and Vial Stands may also be obtained separately.

CASE STUDY: XENON DERIVATIVE & CRYSTAL STRUCTURE

A Xenon Derivative of Tt UvrB Crystal Prepared using the Hampton Research Xenon Chamber

DESCRIPTION

Thermus thermophilus UvrB (Tt UvrB), a 76 kDa protein is a component of the nucleotide excision repair system. The Tt UvrB crystal structures was determined by single isomorphous replacement / anomalous scattering from a xenon derivative. The UvrB crystals were pressurized with 500 psi of xenon gas for 15 minutes at room temperature and flash cooled for data collection. Xenon derivatized crystals diffracted to 1.9 angstrom.

XENON RECOVERY SYSTEM™

APPLICATION

- Scavenge and recover xenon gas from low pressure xenon gas cylinders

FEATURES

- Utilize up to 95% of xenon gas in cylinders

DESCRIPTION

Xenon Gas Pump

When using the Xenon Chamber to obtain derivatized crystals, the gas pressure is typically between 200 and 500 psi. A typical 50 liter compressed xenon gas cylinder has an initial pressure of 600 psi. Without some type of recovery system, if the cylinder pressure is less than desired, the cylinder cannot be used and the expensive xenon gas is wasted. With the Xenon Recovery System connected to a compressed xenon gas cylinder, pressures can be increased by a factor of 9. This means a typical compressed xenon gas cylinder is utilized at 95% efficiency versus 50% efficiency without the recovery system. The system easily connects to the Xenon Chamber and Pressure Regulator. Contact Technical Support for complete specifications.

PENS

TEENY WRITER

APPLICATION

- Marking crystallization plates, labels, sample tubes, and vials

FEATURES

- Fine point writing tip
- Black ink

DESCRIPTION

The Teeny Writer has an extra fine tip. Recommended for writing on all our labels for samples that will be stored at room temperature and not exposed to chemicals and/or caustic agents. Ink dries in a matter of seconds. The ink is NOT resistant to detergents and reagents used in histology procedures. Color: Black.

Order Information

Cat. No.	Name	Description	Price
HR4-462	Teeny Writer	each	$6.00

SOLVENT RESISTANT PEN

APPLICATION

- Marking of labels and samples

FEATURES

- Fast drying, permanent ink
- Red ink or black ink

DESCRIPTION

The Solvent Resistant Pen is recommended for writing on Tough-Tags. The ultra-permanent ink dries in a matter of seconds and resists solvents such as xylene, alcohol, acetone, and formalin. Testing is advised before use.

Order Information

Cat. No.	Name	Description	Price
HR4-464	Solvent Resistant Pen - Black	each	$6.00

TOUGH-TAGS® ON A ROLL

TOUGH-TAGS® ON A ROLL - TEENY

APPLICATION

- Labels for 0.2 ml microtubes

FEATURES

- Pre-cut, peel off labels
- Withstands solvents, incubation in high humidity, and freezing to -40°C
- Works best with extra fine point markers (Teeny Writer)
- Convenient, easy to dispense roll

DESCRIPTION

Designed for use with 0.2 ml microtubes, Tough-Tags On a Roll - Teeny will withstand thermal-cycling, autoclaving, boiling water baths and freezing to -40°C.

Label Size: 0.81" x 0.28" (21 mm x 7 mm)
Color: White; Quantity: 1,500 labels per roll

Order Information

Cat. No.	Name	Description	Price
HR4-458	Tough-Tags® On a Roll - Teeny	1 roll	$35.00

TOUGH-TAGS® ON A ROLL

TOUGH-TAGS® ON A ROLL – SIDEWALL

APPLICATION

- Labels for crystallization plates

FEATURES

- Withstands solvents, incubation in high humidity, and freezing to -20°C
- Easy to peel off and affix
- Pre-cut labels fit perfectly on the side of crystallization plates

DESCRIPTION

Tough-Tags On a Roll - Sidewall have been carefully engineered to strongly adhere to all plastics and other materials. Sidewall Tough-Tags withstand organic solvents, caustic agents, humid incubators, boiling water baths, and freezer temperatures without peeling. These pre-cut labels fit perfectly onto the sides of crystallization plates allowing for visual identification of the individual plates in a stack.

Label Size: 1.50" x 0.25" (38 mm x 6 mm)
Color: White; Quantity: 1,000 labels per roll

Order Information

Cat. No.	Name	Description	Price

CRYO-BABIES® AND CRYO-TAGS® ON A ROLL

APPLICATION

- Labels for cryo labware cryogenic storage

FEATURES

- Freezable in liquid nitrogen
- Chemically resistant
- Made of a special smear-resistant material that will accept any marking instrument
- Pre-cut labels on a roll in dispenser box

DESCRIPTION

CRYO-TAGS
CRYO-BABIES
CRYO-BABIES

Labels for cryogenic storage. Withstand conventional and cryogenic storage (vapor and liquid phase nitrogen storage) to -196°C. The labels will also withstand boiling water baths to 100°C and dry heat up to 150°C. Polyolefin labels adhere to all plastics, glass, and metals. They resist detergents, oils, solvents, caustic agents, and other challenges without peeling or falling off. Great for labeling plastics and other materials for cryogenic storage. Cryo-Babies are ideal for1.5-2.0 ml or larger tubes. Apply label to tube or container BEFORE freezing.

Catalog #HR4-404 Label Size: 1.28" x 0.50" (33 mm x 13 mm)
Catalog #HR4-406 Label Size: 1.50" x 0.75" (38 mm x 19 mm)

TOUGH-SPOTS® ON A ROLL

TOUGH-SPOTS® ON A ROLL - SMALL

APPLICATION

- Circular labels for 0.5 - 2.0 ml tube tops

FEATURES

- For microtube cap or lid identification
- Freezable in liquid nitrogen
- Autoclavable and boilable
- Chemically resistant
- Won't dry out, fall off, or tear

DESCRIPTION

Tough-Spots On a Roll - Small are chemically inert, polyvinyl labels that adhere to all plastics. They are 3/8" diameter circular labels that are useful for tagging and easily identifying a wide range of small containers in the crystallization lab. Available in five different colors.

Label Size: 3/8" diameter (9.5 mm diameter)
Quantity: 1,000 labels per roll

Order Information

TOUGH-SPOTS® ON A ROLL - LARGE

APPLICATION

- Labels for 1.5 - 2.0 ml tube tops

FEATURES

- For microtube cap or lid identification
- Freezable in liquid nitrogen
- Autoclavable and boilable
- Chemically resistant
- Won't dry out, fall off, or tear

DESCRIPTION

Tough-Spots On a Roll - Large are chemically inert, polyvinyl labels that adhere to all plastics. They are 1/2" diameter circular labels that are useful for tagging and easily identifying a wide range of small containers in the crystallization lab.

Label Size: 1/2" diameter (13 mm diameter)
Color: White; Quantity: 1,000 labels per roll

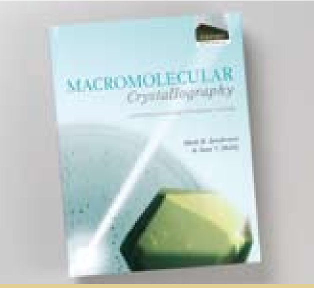
MACROMOLECULAR CRYSTALLOGRAPHY

- Authors: Mark Sanderson and Jane Skelly
- Publisher: Oxford University Press, 2007
- ISBN-10: 0198520972
- ISBN-13: 978-0198520979
- Hardcover: 400 pages

DESCRIPTION



Macromolecular Crystallography - conventional and high-throughput methods

Macromolecular crystallography is the study of macromolecules (proteins and nucleic acids) using x-ray crystallographic techniques in order to determine their molecular structure. The knowledge of accurate molecular structures is a pre-requisite for rational drug design, and for structure-based function studies to aid the development of effective therapeutic agents and drugs. The successful determination of the complete genome (genetic sequence) of several species (including humans) has recently directed scientific attention towards identifying the structure and function of the complete complement of proteins that make up that species; a new and rapidly growing field of study called 'structural genomics'. There are now several important and well-funded global initiatives in operation to identify all of the proteins of key model species. One of the main requirements for these initiatives is a high-throughput crystallization facility to speed-up the protein identification process. The extent to which these technologies have advanced, calls for an updated review of current crystallographic theory and practice. This practical reference book features the latest conventional and high-throughput methods, and includes contributions from a team of internationally recognized leaders and experts. It will be of relevance and use to graduate students, research scientists and professionals currently working in the field of conventional and high-throughput macromolecular crystallography.

Author Information

Mark Sanderson is an experienced protein and nucleic-acid crystallographer and co-editor of Methods in Molecular Biology, who has solved several key ab initio structures, notably nucleic-acid proteins. Jane Skelly has widespread experience in the expression and crystallisation of macromolecules. Both authors lecture undergraduates in structural biology.

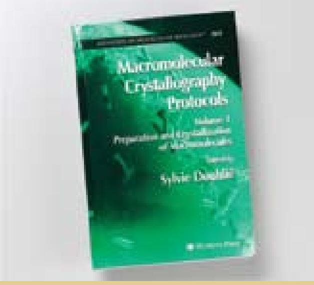
MACROMOLECULAR CRYSTALLOGRAPHY PROTOCOLS, VOLUME 1

- Author: Sylvie Doublie
- Publisher: Humana Press, 2007
- ISBN-10: 1588292924
- ISBN-13: 978-1588292926
- Hardcover: 312 pages

DESCRIPTION



Macromolecular Crystallography Protocols, now in two volumes, examines major developments that have occurred since publication of the acclaimed first edition nearly a decade ago. Volume 1, Preparation and Crystallization of Macromolecules and Volume 2, Structure Determination, explore recent advances that have accelerated the pace of structural determination and made crystallography accessible to a broader range of investigators. Volume 1 is composed of detailed protocols for the preparation and optimization of crystals, including tips from the experts on the best methods for inducing proteins to adopt their crystalline form. Volume 2 complements the first volume by addressing laboratory techniques for crystal handling and structural characterization, as well as computational techniques for data collection, phasing, and refinement. The volume concludes with a detailed and insightful survey of available crystallographic software. These volumes will be an indispensable reference for obtaining macromolecular crystals and determining their three-dimensional structure.

PROTEIN CRYSTALLIZATION STRATEGIES FOR STRUCTURAL GENOMICS

- Editor: Naomi E. Chayen
- Publisher: International University Line, 2007
- ISBN-10: 097207743X
- ISBN-13: 978-0972077439
- Hardcover: 290 pages

DESCRIPTION

Research advances in recent years have opened up the scope for the development of new methods and tools to overcome the bottleneck of protein crystallization. A variety of parameters that could previously not be explored are now accessible thanks to sophisticated apparatus and the development of new science-based techniques to monitor and control the process of crystallization. However, in order to become useful to the structural genomics effort, it is vital to miniaturize and automate these techniques and adapt them to cope with the vast numbers of "leads" resulting from the high-throughput screening procedures. Such efforts are those of the immediate future and the focus of this book.

- ISBN-10: 0124860524
- ISBN-13: 978-0124860520
- Hardcover: 504 pages

DESCRIPTION

Covers all aspects of protein crystallography. It is a practical handbook intended to be used by anyone who wants to solve a structure by protein crystallography. This book is divided into four chapters: (1) Laboratory Techniques; (2) Data Collection Techniques; (3) Computational Techniques; and (4) Protein Crystallography Cookbook.

PREPARATION AND ANALYSIS OF PROTEIN CRYSTALS

- Author: Alexander McPherson
- Publisher: Krieger Publishing, 1989
- ISBN-10: 089464355X
- ISBN-13: 978-0894643552
- Hardcover: 384 pages

DESCRIPTION

This hard-to-find book is a classic. The first text written specifically for macromolecular crystallization. This twelve chapter book provides an interface between the techniques and practices common to most biochemists and the procedures familiar to x-ray diffractionists.

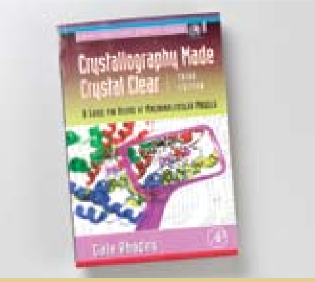
CRYSTALLOGRAPHY MADE CRYSTAL CLEAR

- Author: Gale Rhodes
- Publisher: Academic Press; 3rd edition, 2006
- ISBN-10: 0125870736
- ISBN-13: 978-0125870733
- Paperback: 352 pages

DESCRIPTION



This book is an exciting resource for those who are vitally interested in macromolecular models derived from x-ray crystallography but are unfamiliar with, or daunted by, crystallography itself. This book is for readers who want an intellectually satisfying understanding of how three-dimensional models of proteins and nucleic acids are derived from x-ray diffraction analysis of crystals. This understanding is essential for wise use of crystallographic models in studying enzyme catalysis, protein-mediated transport and recognition, protein/nucleic acid interaction, and protein folding. It is also vital in interpreting data from chemical, kinetic, thermodynamic, and spectroscopic studies of macromolecules.

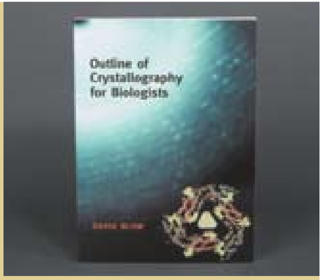
OUTLINE OF CRYSTALLOGRAPHY FOR BIOLOGISTS

- Author: David Blow
- Publisher: Oxford University Press, 2002
- ISBN-10: 0198510519
- ISBN-13: 978-0198510512
- Paperback: 248 pages

DESCRIPTION



Outline of Crystallography for Biologists is intended for researchers and students in the biological sciences who require an insight into the methods of x-ray crystallography without needing to learn all the relevant theory. The main text is purely descriptive and is readable by those with minimal mathematical knowledge. Some mathematical detail is given throughout in boxes, but these can be ignored. Theory is limited to the essentials required to comprehend issues of quality. There is an extensive reference section and suggestions for further reading for those who wish to delve deeper. The first part, 'Fundamentals', presents the underlying ideas which allow x-ray structure analysis to be carried out and provides an appropriate background to courses in structural determination. The second part, 'Practice', gives more information about the procedures employed in the course of crystal structure determination. The emphasis is on the quality measures of x-ray diffraction analysis to give the reader a critical insight into the quality and accuracy of a structure determination and to enable the reader to appreciate which parts of a structure determination may have caused special difficulty. There is no pretence of completeness and many matters discussed in standard crystallography texts are deliberately omitted. However, issues not brought out in the standard texts are discussed, making it a useful resource for non-practicing crystallographers as well.

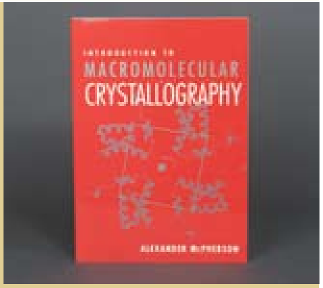
INTRODUCTION TO MACROMOLECULAR CRYSTALLOGRAPHY

- Author: Alexander McPherson
- Publisher: Wiley-Blackwell; 2nd edition, 2009
- ISBN-10: 0470185902
- ISBN-13: 978-0470185902
- Paperback: 267 pages

DESCRIPTION



This book provides a comprehensive, approachable summary of the field of crystallography, from the fundamental theory of diffraction and properties of crystals to applications in determining macromolecular structure.

Dedicated to providing a complete introduction to the subject that does not assume a background in physics or math, the book's contents flow logically from basic principles to key methods, such as those for solving phase problems, interpretation of Patterson maps, and the difference Fourier method. The Introduction includes: Practical Instruction on the Interpretation of Data and Methods for Determining Phases.

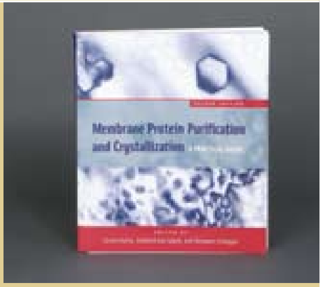
MEMBRANE PROTEIN PURIFICATION & CRYSTALLIZATION, A PRACTICAL GUIDE

- Editors: Carola Hunte, Gebhard Von Jagow, Hermann Schagger
- Publisher: Academic Press; 2nd edition, 2002
- ISBN-10: 0123617766
- ISBN-13: 978-0123617767
- Spiral-bound: 316 pages

DESCRIPTION



This guide presents isolation and crystallization techniques in a concise form, emphasizing the critical aspects unique to membrane proteins. It explains the principles of the methods and provides protocols of general use, permitting researchers and students new to this area to adapt these techniques to their particular needs. Key features: Provides general guidelines and strategies for isolation and crystallization of membrane proteins. Gives detailed protocols that have wide application, and low specialized equipment needs. Emphasizes recent progress in production and purification of recombinant membrane proteins, especially of histidine-tagged and other affinity-epitope-tagged proteins. Summarizes recent developments of Blue-Native PAGE, a high resolution separation technique, which is independent of the use of recombinant techniques, and is especially suited for proteomic analyses of membrane protein complexes. Gives detailed protocols for membrane protein crystallization, and describes the production and use of antibody fragments for high resolution crystallization. Presents a comprehensive guide to 2D-crystallization of membrane proteins.

METHODS AND RESULTS IN CRYSTALLIZATION OF MEMBRANE PROTEINS

- Editor: So Iwata
- Publisher: International University Line, 2002
- ISBN-10: 0963681796
- ISBN-13: 978-0963681799
- Hardcover: 380 pages

DESCRIPTION

This text consists of four parts. Parts 1 and 2 include an introduction as well as general principles and techniques in membrane protein crystallization. This is followed by chapters covering the use of detergents, crystallization in lipidic cubic phases, the use and generation of antibody fragments, porin as a model, and crystallization of membrane proteins in oils. Part 3 focuses on specific examples of membrane proteins whose structures have been solved. Part 4 covers the design of a kit for membrane protein crystallization.

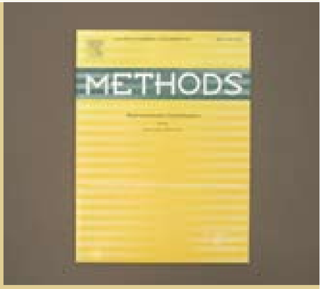
MACROMOLECULAR CRYSTALLIZATION METHODS, VOLUME 34, NUMBER 3

- Edited by: Alexander McPherson
- Publisher: Elsevier; Methods, Volume 34, Number 3, November 2004
- ISSN: 1046-2023
- Paperback: 172 pages

DESCRIPTION



This is a single issue of Methods, a companion journal to Methods in Enzymology, focusing on rapidly developing techniques. This single issue is dedicated to Macromolecular Crystallization and begins with an Introduction to Protein Crystallization by Alexander McPherson. The issue features the following additional thirteen articles. Protein crystallization and phase diagrams, Neer Asherie. Growth and disorder of macromolecular crystals: insights from atomic force microscopy and x-ray diffraction studies, Alexander J. Malkin and Robert E. Thorne. Ions from the Hofmeister series and osmolytes: effects on proteins in solution and in the crystallization process, Kim D. Collins. Effects of naturally occurring osmolytes on protein stability and solubility; issues important in protein crystallization, D.W. Bolen. Practical aspects of using the microbatch method in screening conditions for protein crystallization, Allan D'Arcy, Aengus Mac Sweeney, and Alexander Haber. Automated systems for protein crystallization, Joel Bard, Kimberly Ercolani, Kristine Svenson, Andrea Olland, and Will Somers. Lipidic cubic phases as matrices for membrane protein crystallization, Peter Nollert. The use of recombinant and molecular engineering in protein crystallization, Zygmunt Derewenda. A pedestrian guide to membrane protein crystallization, Michael Wiener. Crystallization data mining in structural genomics: using positive and negative results to optimize protein crystallization screens, Rebecca Page and Raymond C. Stevens. Predictive models for protein crystallization, Bernhard Rupp and Junwen Wang. Crystallization of RNA and RNA-protein complexes, Ailong Ke and Jennifer A. Doudna. Macromolecular cryocrystallography – methods for cooling and mounting protein crystals are cryogenic temperatures, J.W. Pflugrath.

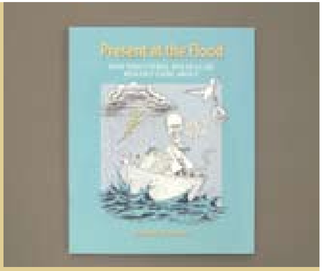
- Paperback: 307 pages

DESCRIPTION



This book chronicles a revolution in molecular biology—the crucial 30 years (roughly between 1933 and 1963) during which our ideas about proteins and nucleic acids changed from those of formless, functionless organic chemicals into precisely structured molecular machines with specific biological purpose. Proteins evolved from being colloidal micelles or globules with no specific structure (or even sequence) into quite precisely structured molecular catalysts, carrier proteins, and information-sensing agents. Indeed, the very idea that the amino acids of a protein were linked in a specific order in long linear chains was not accepted initially. During this same time period, DNA changed from being a sterile repeating polymer of no particular function (the tetranucleotide hypothesis) into a double helix that serves as the archive of genetic information.

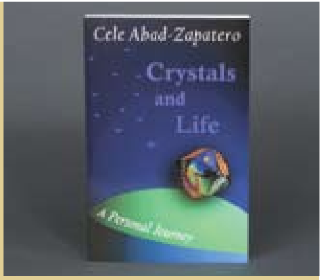
CRYSTALS AND LIFE: A PERSONAL JOURNEY

- Author: Cele Abad-Zapatero
- Publisher: International University Line, 2002
- ISBN-10: 0972077405
- ISBN-13: 978-0972077408
- Paperback: 300 pages

DESCRIPTION



This book introduces crystallography, the field, and applications of structural biology using metaphors from the arts, music, poetry, and architecture. The reader will find a tapestry filled by personal experiences, historical anecdotes, biographical snapshots of scientific heroes of the field, and crystallographic concepts illustrated with artistic analogies. All these elements create a concoction that makes crystallography accessible, comprehensible, intriguing, inspiring, and beautiful. The book is divided in sections covering the following: the basic elements of crystallography, novel technologies, practical applications and future perspectives. Since crystallography is quintessentially a visual science, the illustrations play a very important role in providing an excellent set of landmarks to guide the reader on this personal journey of discovery.

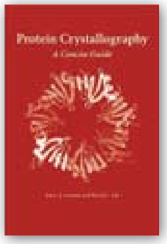
PROTEIN CRYSTALLOGRAPHY: A CONCISE GUIDE

- Authors: Eaton E. Lattman and Patrick J. Loll
- Publisher: The Johns Hopkins University Press, 2008
- ISBN-10: 0801888085
- ISBN-13: 978-0801888085
- Paperback: 152 pages

DESCRIPTION



The proteome remains a mysterious realm. Researchers have determined the structures of only a small fraction of the proteins encoded by the human genome. Crystallography continues to be the primary method used to determine the structures of the remaining unknown proteins. This imaging technique uses the diffraction of x-rays to determine a protein's three-dimensional molecular structure. Drawing on years of research and teaching experience, Eaton E. Lattman and Patrick J. Loll use clear examples and abundant illustrations to provide a concise and accessible primer on protein crystallography. Discussing the basics of diffraction, the behavior of two- and three-dimensional crystals, phase determination (including MIR and MAD phasing and molecular replacement), the Patterson function, and refinement, Lattman and Loll provide a complete overview of this important technique, illuminated by physical insights. The crisp writing style and simple illustrations will provide beginner crystallographers with a guide to the process of unraveling protein structure.

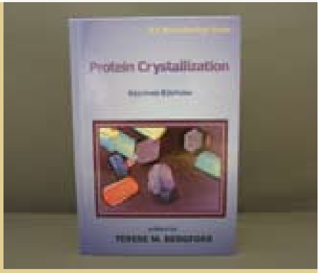
PROTEIN CRYSTALLIZATION

- Editor: Terese Bergfors
- Publisher: International University Line; 2nd edition, 2009
- ISBN-10: 0972077448
- ISBN-13: 978-0972077446
- Hardcover: 474 pages

DESCRIPTION



Completely revised and updated, Protein Crystallization, 2nd Edition is a greatly expanded follow-up to the best-selling 1st edition. Completely new chapters on high-throughput methods, mass spectrometry, microcalorimetry, counterdiffusion, heavy-atom derivatization, selenomethionine-labeling, rational strategies for crystallization, and protein modification to improve crystallization. Updated chapters on formulation of the protein before crystallization, characterization of the protein by dynamic light scattering, classic methods and the phase diagram, seeding, and cryoprotection of the crystals. Thirty full-color plates for evaluating crystallization drops. Separate section of laboratory exercises, ideal for crystallization courses. A-Z glossary.

GLUCOSE ISOMERASE

APPLICATION

- Crystallization grade protein standard

FEATURES

- Protein standard for crystallization studies and applications
- Crystallization training and student demos

DESCRIPTION

Glucose Isomerase can be crystallized by sitting, hanging or sandwich drop vapor diffusion, batch, liquid/liquid diffusion, pH shift, temperature jump, as well as by dialysis. It can be crystallized rapidly across a broad range of screen conditions which makes the enzyme an excellent candidate for crystallization studies and demonstrations. Glucose Isomerase is supplied as a crystal suspension in the following medium: Approximately 33 mg/ml in 6 mM TRIS hydrochloride pH 7.0, 0.91 M Ammonium sulfate, 1 mM Magnesium sulfate. Glucose Isomerase is prepared by Macrocrystal Oy, exclusively for Hampton Research.

Glucose Isomerase catalyzes the isomerization reaction shown. The reaction is reversible and goes to equilibrium, approximately equal concentrations of fructose and glucose.

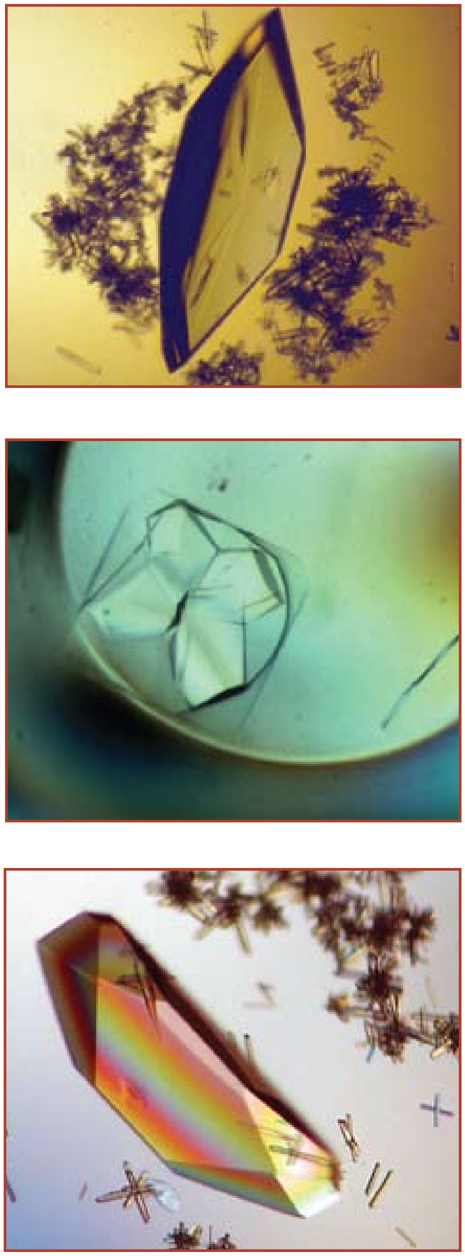
LYSOZYME

APPLICATION

- Crystallization grade protein standard

FEATURES

- Protein standard for crystallization studies and applications
- Crystallization training and student demos
- Hen egg white source



Lysozyme crystals grown using the Hampton Research Silver Bullets screen

DESCRIPTION

A very cost-effective and convenient crystallization grade lysozyme (hen egg white). The Lysozyme Kit is a convenient buffer and lysozyme set for teaching, demonstrations or instrumentation setup and validation procedures. The kit features 12 vials with 20 mg of lysozyme and 12 vials of 0.02 M Sodium acetate trihydrate pH 4.6 buffer. To prepare the lysozyme for crystallization, simply add the supplied buffer to the protein. No weighing, no messing with fluffy crystalline powder, no mess, and no variability. Each tube can make up to 1 ml of a 20 mg/ml stock or 200 μl of a 100 mg/ml stock. Twelve sets of tubes and a stable shelf life make this a handy kit to keep in the fridge. Lysozyme is available separately in an 8 g vial of lysozyme powder. To dissolve the powder, use the Lysozyme Crystallization Buffer. For teaching and demonstrations requiring crystals in a short period of time, one should consider the 15-Minute Lysozyme Crystallization Reagent (30% w/v Polyethylene glycol monomethyl ether 5,000, 1.0 M Sodium chloride, 0.05 M Sodium acetate trihydrate pH 4.6). For flexibility, one can also use the Lysozyme Crystallization Buffer stock (1.0 M Sodium acetate trihydrate pH 4.6) or the StockOptions Sodium Acetate buffer kit and 5.0 M Sodium chloride to create custom grid screens and practicals for demonstrating and teaching the fundamentals of optimization of sample concentration and reagent concentration. The Grid Screen Sodium Chloride kit is a convenient kit for demonstrating the effect of varying pH and reagent concentration on the solubility and crystallization of a protein.

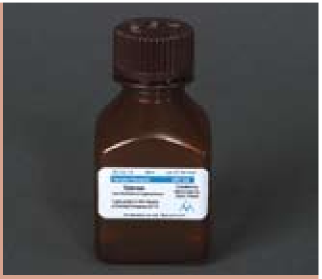
Xylanase Crystals

DESCRIPTION



Xylanase can be crystallized by sitting, hanging or sandwich drop vapor diffusion, batch, liquid/liquid diffusion, pH shift, temperature jump, as well as by dialysis. It can be crystallized rapidly across a broad range of screen conditions which makes the enzyme an excellent candidate for crystallization studies and demonstrations. It is supplied as a solution, produced by dissolving pure xylanase crystals with phosphate buffer and glycerol. The solution is filtered with a 0.2 micron filter and has the final formulation:

Xylanase Concentration: 36 mg/ml
Absorbance at 280 nm: 97
Activity: 648,000 nkat/ml
Glycerol Concentration: 43% w/v
Na/K phosphate: 0.18 M
pH: 7
Specific Gravity: 1.124 g/ml

Xylanase is prepared by Macrocrystal Oy, exclusively for Hampton Research.

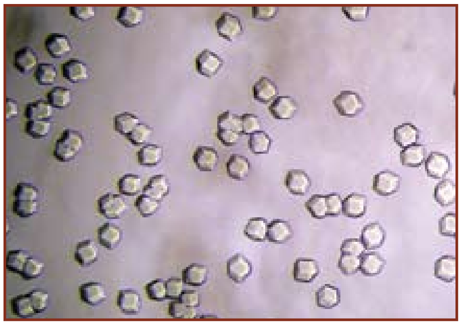
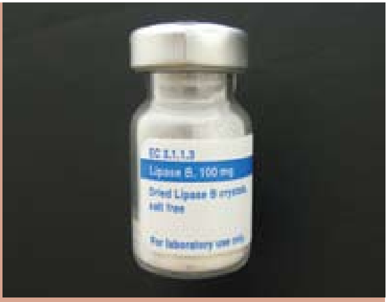
Lipase B Crystals



Lipase B Crystals Grown by Macrocrystal Oy

DESCRIPTION



Lipase B is a pure, dried, crystalline form of Lipase B from Candida antarctica produced by submerged fermentation of a genetically modified Aspergillus oryzae microorganism. It is a white crystal powder where Lipase B is present as crystals and there are no other ingredients or buffering salts.

Lipases (EC 3.1.1.3) make up a diverse group of water soluble enzymes that catalyze the hydrolysis of ester bonds in water–insoluble, lipid substrates. Lipases are characterized by their drastically increased esterase activity when adsorbed to a lipid surface (interfacial activation). Lipases are a form of esterases. They perform essential roles in the digestion, transport, and processing of dietary lipids such as triglycerides, fats, oils in most, if not all, living organisms.

Chemical name, synonym Triacylglycerol hydrolase EC 3.1.1.3
M_r 35 kDa
pH 5.0 - 7.0
Isoelectric point 6.0
Appearance: White crystal powder

Lyophilization

Avoid lyophilization. Even though there are many examples of proteins which crystallize after lyophilization (lysozyme, thaumatin, hemoglobin, etc.), lyophilization is to be avoided when possible. If the protein is lyophilized, it needs to be dialyzed before crystallization. Dialyze the protein against deionized water or a stabilization buffer before crystallization. Dialysis will remove non-volatile buffers and other chemicals that may have been present before lyophilization.

Ammonium Sulfate Precipitation

Avoid using Ammonium sulfate precipitation as a final purification and/or concentration step. It is often very difficult to completely remove all the Ammonium sulfate by a desalting column of dialysis. The remaining trace amounts can interfere with crystallization screening results and create reproducibility problems. It is not uncommon for trace amounts of Ammonium sulfate in the sample to cause precipitation or excessive nucleation in screen conditions containing polyethylene glycol and salt.

Batches

Avoid combining different purification batches for crystallization trials. Purification conditions and procedures are never identical so each batch should be screened separately.

Profile the Protein

Ideally, you will purify your own protein, but this is not always reality. So, it is always a good idea to characterize your protein before beginning crystallization experiments. Profiling your protein before crystallization can often provide valuable clues during screening and optimization of crystallization conditions. Assay to seriously consider:

- SDS-PAGE
- Native PAGE or Dynamic Light Scattering
- IEF (Isoelectric Focusing) Gel
- Mass Spectroscopy

The results of these assays can:

- Determine the purity of the sample
- Determine the homogeneity of the sample
- Identify batch to batch variations
- Identify stability problems with the sample

How Pure?

How pure should the protein sample be for crystallization trials? As pure as possible. That's some answer, is it not? Integrating common sense into the question, we might arrive at the following answer. For initial screening, the sample should be at least 90 to 95% pure on a Coomassie stained SDS-PAGE. Finally, it does no harm to screen an "impure sample" as one can always perform further purification. Remember, crystallization used to be considered a very powerful purification tool (and still is!).

If the initial screen does not produce crystals, any promising results, or it becomes next to impossible to improve crystal quality during optimization, one should consider further purification of the sample.

Storing the Sample

Most proteins can be stored successfully at 4°C or -70°C.

Check with the person preparing the protein or compare your protein to a similar protein in the literature for best storage temperature.

Ideally, one should assay the activity and stability of the protein before storage and then later on at various points in time to determine the sample storage stability.

Repeated freezing and thawing of the sample should be avoided. Aliquot the sample into multiple small microcentrifuge tubes. Make the aliquots small enough so that the entire aliquot can be consumed in the experiment after thawing.

Sometimes people like to add Glycerol (10 to 50% v/v) to help proteins better tolerate freezing. Avoid this if possible since it is often difficult to remove Glycerol by dialysis or filtration. The presence of Glycerol is a crystallization variable. It can behave as a precipitant, an additive, or cryoprotectant and therefore can influence the outcome of a crystallization experiment.

In general, it is better to store proteins more concentrated than diluted. When too dilute, adsorption of the protein onto the storage container can lead to significant losses. However, precipitation can sometimes be a problem when the protein is stored too concentrated.

Sample Handling

Be nice to your protein. Remember that proteins make an excellent food source for microbes. Protect your sample from microbes by storing the protein at less than 4°C and not leaving it for extended periods of time at room temperature.

When thawing a sample or mixing a lyophilized sample into solution, do not shake or vortex the protein. Avoid foaming the sample. Foam can be a sign of denaturation.

Allow the sample to equilibrate to the temperature where the crystallization experiments will be set up and/or incubated before setting the experiment.

The field of crystal growth is full of opinions and controversy. There are several opinions on what should be done with the sample just prior to setting the crystallization experiment. Let's have a look at those opinions.

Some like to filter the sample through a 0.2 micron (or smaller, but be sure to compare the MW of your sample to the pore size of your filter so as not to stick your sample on the filter) pore size filter into a sterile container. Filtration can remove microbial contamination (but not the proteases) as well as sample aggregation. Turbid sample solutions with lots of precipitate should be solubilized or centrifuged before filtration to avoid the ugly experience of sticking the sample to a filter membrane. Use filters with the smallest possible dead volume to minimize sample loss. Some of the centrifugal microfiltration devices are certainly worth consideration. Before filtering the sample, wash or flush the filter with a small amount of the sample buffer/storage solution. This will test the filter for compatibility with your sample buffer and remove any trace glycerol which can sometimes be present from the manufacturer. If possible, test filter a small aliquot of the sample, and measure the activity/OD before filtering the entire sample. Do this to test the adherence of the sample to the filter media. Read and follow the instructions supplied with the filter before introducing the sample to the filter.

Some like to centrifuge the sample. Centrifugation removes large sample aggregates and amorphous debris. Post centrifugation views can provide a visual clue of aggregation/precipitate for seemingly clear solutions. Following centrifugation, use only the supernatant for crystallization trials.

Others prefer to avoid filtration or centrifugation before setting crystallization experiments. One view is that the presence of amorphous material or aggregates can enhance the changes for crystallization by acting as nucleants.

To Azide or Not

Sodium azide (NaN^3) is an anti-microbial preservative that is sometimes used to protect samples and crystallization reagents from microbial contamination. Sodium azide is toxic and should be handled with care. Typical Sodium azide concentrations are 1 mM or if you prefer % measurements, between 0.02% and 0.1% w/v.

If you choose to use Sodium azide remember that:

- It is toxic to humans as well as microbes.
- It is an inhibitor for some proteins and may become an unintentional ligand for your sample.
- It can interfere with heavy atom derivatization.
- Some metal azides are explosive.
- There are reports where eliminating Sodium azide from the experiment improved crystallization.

Alternatives to Sodium Azide include Thymol & Thimerosal.

A final alternative to the use of antimicrobials is the use of proper sterile technique and materials. Sterile filter all samples and reagents into sterile containers. Store samples and reagents at 4°C or lower. Use sterile pipet tips. Keep your work area clean. Develop a sterile technique with your crystallization setups. With common sense, sterile reagents and sample, good technique, and sterile pipet tips, one can successfully avoid the use of chemical antimicrobials in the crystallization lab.

Label & Organize Samples

Label samples clearly with the sample identification, batch identification, and date of storage. Small cryo labels can be very useful here. Color coding samples can be a nice organization tool. For the sake of easy organization and identification, it is sometimes more convenient to nest samples. For example, store batches of small microcentrifuge tubes in 10 ml or 50 ml centrifuge tubes and organize them by batch or sample.

It is prudent to write down and hold onto detailed notes concerning the purification, storage, and handling of the sample. It is obvious that one should also maintain records of crystallization trials which should include:

- Sample information
- Name of sample
- Sample identification (batch, storage location, storage temperature, etc.)
- Sample buffer composition, additives, ligands, etc.
- Sample concentration
- Crystallization experiment information
- Method
- Drop size and composition
- Reagent composition
- Temperature
- Date
- Name of person performing experiment

Questions to Ponder about the Sample

- Does a similar sample exist and has it been crystallized?
- Does the sample contain free cysteines?
- Does the sample contain additives such as Sodium azide, ligands, inhibitors, or substrates?
- Is the protein glycosylated?
- Is the protein phosphorylated?
- Is the protein N-terminal methylated?
- At what temperature is the protein stable?
- How does sample solubility and stability change temperature?
- How does sample solubility and stability change with pH?
- Does the sample bind metals?
- Is the protein sensitive to proteolysis?
- What class of protein am I working with (antibody, virus, enzyme, membrane protein)?
- What have been the most successful approaches with my class of protein?
- What is the source of the sample?
- How was the sample purified and stored before it arrived into my hands?
- What is in the sample container besides the sample (buffer, additives, etc.)?
- Is the sample pooled purification aliquots or a single batch?
- How much sample do I have and how much more is available?
- How pure is the sample?
- How homogeneous is the sample?
- Does anyone possess any solubility information on this sample?
- What is unique about this protein?
- What is necessary chemically and physically to maintain a stable, active sample?

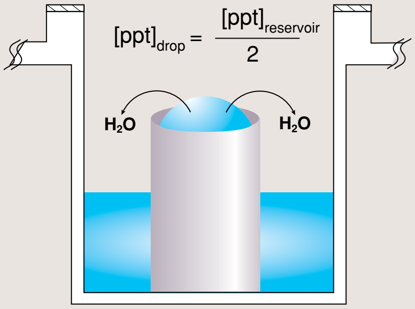
There are several techniques for setting up crystallization experiments (often termed "trials"), including sitting drop vapor diffusion, hanging drop vapor diffusion, sandwich drop, batch, microbatch under oil, dialysis, and free interface diffusion. Here we offer an overview of these crystallization techniques.

Sitting & Hanging Drop Crystallization

Sitting and hanging drop methodologies are very popular because they are easy to perform, require a small amount of sample, and allow a large amount of flexibility during screening and optimization.

Using the sitting drop technique (figure 1), one places a small (0.1 to 40 µl) droplet of the sample mixed with crystallization reagent on a platform in vapor equilibration with the reagent. The initial reagent concentration in the droplet is less than that in the reservoir. Over time the reservoir will pull water from the droplet in a vapor phase such that an equilibrium will exist between the drop and the reservoir. During this equilibration process, the sample is also concentrated, increasing the relative supersaturation of the sample in the drop.

figure 1

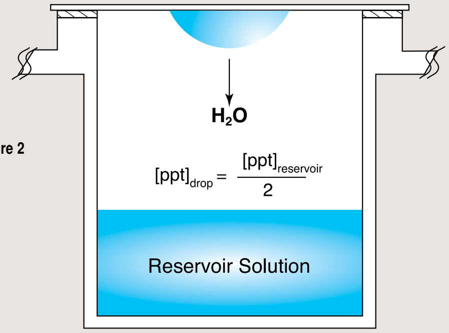


The advantages of the sitting drop technique include speed and simplicity. The disadvantages are that crystals can sometimes adhere to the sitting drop surface making removal difficult. This disadvantage can turn into an advantage where occasionally the surface of the sitting drop can assist in nucleation. The sitting drop is an excellent method for screening and optimization. During production, if sticking is a problem, sitting drops can be performed in the Sandwich Box Setup.

Sitting drop crystallization may be performed using Micro-Bridges® or Glass Sitting Drop Rods™ with VDX™ or Linbro® plates. Both plates can be sealed with clear sealing tape or plain cover slides for easy viewing and access. Sitting drop crystallization may also be preformed using the Cryschem™ Plate. The Cryschem Plate is a specially designed plate with a post already in the center of the reservoir. Finally, sitting drop crystallization can also be performed using one of the 48 or 96 well plates made by Art Robbins Instruments (Intelli-Plate™), Corning (CrystalEX™), Douglas Instruments (CrystalClear Strips™), Greiner (CrystalQuick™), or Swissci (MRC).

Using the hanging drop technique (figure 2), one places a small (0.1 to 20 µl) droplet of the sample mixed with crystallization reagent on a siliconized glass cover slide inverted over the reservoir in vapor equilibration with the reagent. The initial reagent concentration in the droplet is less than that in the reservoir. Over time the reservoir will pull water from the droplet in a vapor phase such that an equilibrium will exist between the drop and the reservoir. During this equilibration process, the sample is also concentrated, increasing the relative supersaturation of the sample in the drop.

figure 2

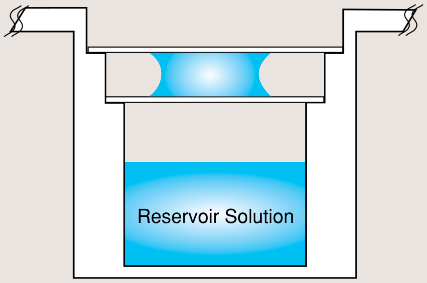


The advantages of the hanging drop technique include the ability to view the drop through glass without the optical interference from plastic, flexibility, reduced chance of crystals sticking to the hardware, and easy access to the drop. The disadvantage is that a little extra time is required for setups.

Sandwich Drop Crystallization

The sandwich drop crystallization method is illustrated in figure 3. The sample solution that is mixed with the precipitant is placed in the middle of a lower siliconized glass cover slide. A siliconized glass cover slide is then set in position along an upper edge. This allows for a small amount of space between the cover slides but is close enough so the drop is sandwiched between them. This technique offers an alternate equilibration method. However, the set up can be tedious and the plates designed for this method typically have a larger footprint than most.

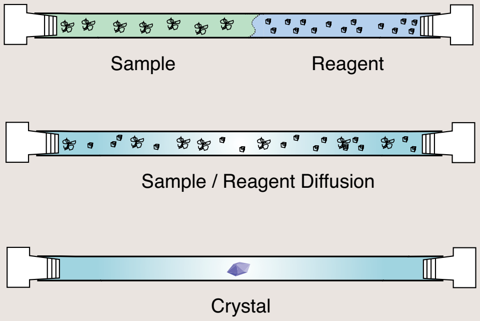
figure 3



Free Interface Diffusion

Free interface diffusion crystallization is used less frequently than sitting or hanging drop vapor diffusion but it is one of the methods used by NASA in microgravity crystallization experiments and at least one company has automated and miniaturized the method. Using this method, one actually places the sample in liquid contact with the precipitant. When doing so, one attempts to create a clearly defined interface between the sample and the precipitant. Over time the sample and precipitant diffuse into one another and crystallization may occur at the interface, or on the side of high sample/low precipitant or low sample/high precipitant. The technique allows one to screen a gradient of sample precipitant concentration combinations. The technique can readily be performed in small

figure 4



capillaries (figure 4).

Batch

Batch crystallization is a method where the sample is mixed with the precipitant and appropriate additives, creating a homogeneous crystallization medium requiring no equilibration with a reservoir. The technique is popular with small molecule crystallographers. The advantages to the technique are speed and simplicity but the disadvantage is that only a narrow space of precipitant/sample concentration can be sampled in a single experiment. A batch experiment can be readily performed in a capillary, small container, or plate with a small reservoir. One must be very close to the conditions which promote crystal growth in order for this technique to be successful.

Microbatch Under Oil

In this technique, a small drop of the sample combined with the crystallization reagent is pipetted under a layer of oil. For a true microbatch, the drop is placed under paraffin oil (figure 5) which allows little to no evaporation, nor concentration in the drop. A modified microbatch can be performed when the drop is placed under a mixture of paraffin oil and silicon oil, or straight silicon oil (figure 6). Such oils permit water vapor to permeate from the drop and allow sample and reagent to concentrate. Unless the drop is equilibrated with a reservoir, water will leave the drop until only solids remain.

The benefits of crystallization under oil include the use of very small sample and reagent volumes with less concern for unwanted evaporation, the minimization of surface interaction with the sample, the ability to precisely control sample and reagent concentrations during the experiment, and the minimization of condensation during temperature fluctuations.

figure 5

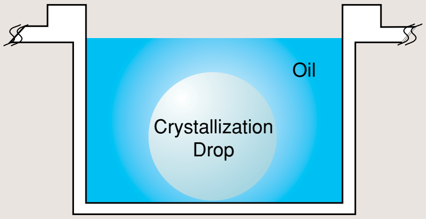


figure 6

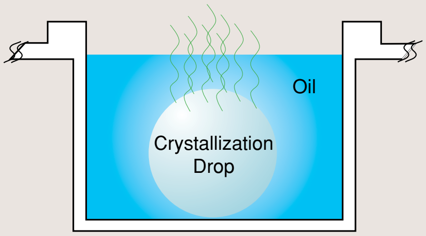

Dialysis Crystallization

Dialysis crystallization involves placing the sample in a Dialysis Button™ which is sealed with a dialysis membrane. Water and some precipitants are then allowed to exchange while retaining the sample in the cell. The Dialysis Button is placed into a suitable container holding the precipitant or crystallization media (figure 7). For example, one might dialyze a sample requiring a high ionic strength for solubility against a solution of low ionic strength. The technique allows for salting in and salting out, as well as pH crystallization techniques.

HANGING DROP VAPOR DIFFUSION CRYSTALLIZATION

Solutions for Crystal Growth

The hanging drop vapor diffusion technique is a very popular method for the crystallization of macromolecules. The principle of vapor diffusion is straightforward. A drop composed of a mixture of sample and reagent is placed in vapor equilibration with a liquid reservoir of reagent. Typically the drop contains a lower reagent concentration than the reservoir. To achieve equilibrium, water vapor leaves the drop and eventually ends up in the reservoir. As water leaves the drop, the sample undergoes an increase in relative supersaturation. Both the sample and reagent increase in concentration as water leaves the drop for the reservoir. Equilibration is reached when the reagent concentration in the drop is approximately the same as that in the reservoir.

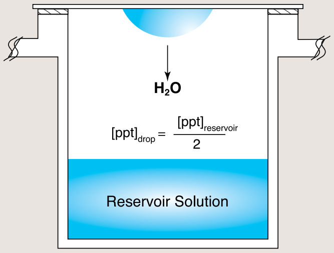

figure 1
Process of Vapor Diffusion

Benefits of Hanging Drop Crystallization

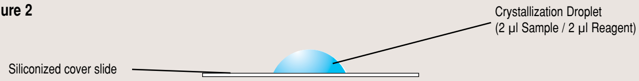
- Can be cost-effective.
- Sample and reagents in contact with a siliconized glass surface.
- Easy access to crystals.
- Can perform multiple drops (experiments) with a single reservoir.
- Good optics for viewing experiments.

Using the VDX™ Plate

The VDX Plate is a 24 well plate manufactured from clear polystyrene. It is typically sealed with vacuum grease (HR3-510) and siliconized 22 mm circle or square glass cover slides. The VDX Plate is also available with sealant which is a convenient time saver. Rows of the plate are labeled A-D and columns are labeled 1-6.

1. Apply a bead of vacuum grease along the top edge of the raised reservoir A1 of the VDX Plate. It is recommended that one apply the vacuum grease prior to pipetting the reagent. Create a circular bead on the upper edge of the reservoir. Do not complete the circle. Leave a 2 mm opening between the start and finish of the circular bead. Apply the cover slide, press to relieve the air pressure and twist to close the gap. Or simply use the VDX Plate with sealant. These plates come pregreased.

figure 2



2. Pipet 1.0 ml of crystallization reagent into reservoir A1 of the VDX Plate. *(Note: Recommended reservoir volume is 0.5 to 1.0 ml)*
3. Clean a siliconized 22 mm circle or square cover slide by wiping it with lens paper and blowing it with clean, dry compressed air. Pipet 1 µl of sample into the center of a siliconized 22 mm circle or square cover slide. *(Note: Recommended total drop volume is 0.1 to 20 µl)*
4. Pipet 1 µl of reagent from reservoir A1 into the drop on the cover slide containing the sample. *(Note: Some prefer to mix the drop while others do not. Proponents of mixing leave the pipet tip in the drop while gently aspirating and dispensing the drop with the pipet. Mixing ensures a homogeneous drop and consistency drop to drop. Proponents of not mixing the drop simply pipet the reagent into the sample with no further mixing.)*
5. Holding the cover slide with forceps, the PEN-VAC®, Cover Slide Vacuum Gadget™, or on the edge between your thumb and forefinger, carefully yet without delay, invert the cover slide so the drop is hanging from the cover slide.
6. Position the cover slide onto the bead of grease on reservoir A1. Gently press the slide down onto the grease and twist the slide 45° to ensure a complete seal.
7. Repeat for reservoirs 2 through 24.

VDX Plate Tips

- Note the VDX Plate has a raised cover to protect the cover slides during transport and storage.
- To access a drop and/or reservoir, simply grasp the edge of the cover slide with forceps or fingertips, twist and pull gently.
- VDX Plates can be stacked for convenient storage.
- One can pipet multiple drops onto the cover slide. This technique is often useful when screening additives since one can use the same reservoir with multiple drops with each drop containing a different additive. This technique can also be used to screen different drop sizes and ratios versus the same reservoir. Use care to avoid mixing the drops during pipetting, plate transport, and plate viewing.
- The 0.96 mm Thick glass cover slides or the plastic cover slides are very durable and most tolerant to rough handling.

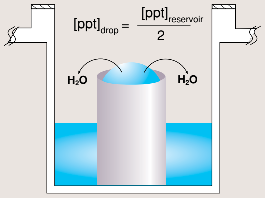
SITTING DROP VAPOR DIFFUSION CRYSTALLIZATION

The sitting drop vapor diffusion technique is a popular method for the crystallization of macromolecules. The principle of vapor diffusion is straightforward. A drop composed of a mixture of sample and reagent is placed in vapor equilibration with a liquid reservoir of reagent. Typically the drop contains a lower reagent concentration than the reservoir. To achieve equilibrium, water vapor leaves the drop and eventually ends up in the reservoir. As water leaves the drop, the sample undergoes an increase in relative supersaturation. Both the sample and reagent increase in concentration as water leaves the drop for the reservoir. Equilibration is reached when the reagent concentration in the drop is approximately the same as that in the reservoir.

figure 1
Process of Vapor Diffusion



Benefits of Sitting Drop Crystallization

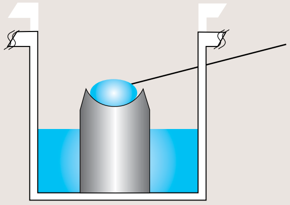
- Can be cost-effective.
- Can be time-efficient.
- Often easier when using detergents, organics and hydrophobic reagents.
- Drops can be positioned in a stable sitting position.
- Compatible with gels.

Using the Cryschem™ Plate

The Cryschem Plate is a 24 well plate manufactured from clear polystyrene. Each well contains a post in the center which is elevated above the bottom of the reservoir. The smooth, concave depression in the post can hold up to 40 µl drops and the reservoir can hold up to 1.2 ml of reagent. The Cryschem Plate is sealed with either clear sealing tape or film, or plain 22 mm circle or square glass cover slides. Rows are labeled A-D and columns are labeled 1-6.

1. Pipet 0.7 ml of crystallization reagent into reservoir A1 of the Cryschem Plate. *(Note: Recommended reservoir volume is 0.5 to 1.0 ml)*
2. Pipet 1 µl of sample into the post of reservoir A1. *(Note: Recommended total drop volume is 0.1 to 40 µl)*
3. Pipet 1 µl of reagent from reservoir A1 into the drop in post A1. *(Note: Some prefer to mix the drop while others do not. Proponents of mixing leave the pipet tip in the drop while gently aspirating and dispensing the drop with the pipet. Mixing ensures a homogenous drop and consistency drop to drop. Proponents of not mixing the drop simply pipet the reagent into the sample with no further mixing.)*
4. Repeat steps 1 through 3 for the remaining 23 reservoirs.
5. Seal the Cryschem Plate with clear sealing tape or film.

figure 2



Crystallization Droplet
(2 µl Sample / 2 µl Reagent)

Cryschem Plate Tips

- Use Crystal Clear Sealing Tape to seal two rows at a time.
- To access a drop and/or reservoir of a Cryschem Plate sealed with tape, simply make a circular incision in the tape using the inside of the reservoir as a guide. Use a sharp blade to cut the tape and hold the incised piece of tape with forceps. The opening can be sealed with another strip of tape or a plain 22 mm circle or square glass cover slide and vacuum grease.

Using Micro-Bridges®

The Micro-Bridge is a small bridge (inverted U) manufactured from clear polystyrene or clarified polypropylene which contains a smooth, concave depression in the center of the top region of the bridge (figure 3). The Micro-Bridge can hold up to 40 µl drops. It is inserted into the reservoirs of VDX™ or Linbro® plates to perform a sitting drop vapor diffusion experiment. The design is such that the bridge is quite stable in the reservoir and does not require the Micro-Bridge to be bonded to the plate. The Micro-Bridge can be removed from the plate for crystal manipulation and observation if desired.

1. Pipet 1.0 ml of crystallization reagent into reservoir A1 of a VDX plate. *(Note: Recommended reservoir volume is 0.5 to 1.0 ml)*
2. Place a clean (blow the Micro-Bridge with clean, dry compressed air before use) Micro-Bridge into the bottom of reservoir A1 such that the concave depression in the Micro-Bridge is facing up.
3. Pipet 1 µl of sample into the Micro-Bridge in reservoir A1. *(Note: Recommended total drop volume is 0.1 to 40 µl)*
4. Pipet 1 µl of reagent from reservoir A1 into the drop in the Micro-Bridge A1. *(Note: Some prefer to mix the drop while others do not. Proponents of mixing leave the pipet tip in the drop while gently aspirating and dispensing the drop with the pipet. Mixing ensures a homogenous drop and consistency drop to drop. Proponents of not mixing the drop simply pipet the reagent into the sample with no further mixing.)*
5. Repeat steps 1 through 3 for the remaining 23 reservoirs.
6. Seal the plate with clear sealing tape or sealant and plain glass cover slides.

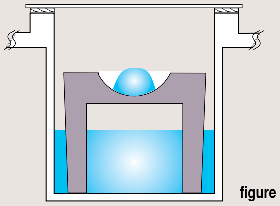


figure 3

Micro-Bridge Tips

- To access a drop and/or reservoir sealed with tape, simply make a circular incision in the tape using the inside of the reservoir as a guide. Use a sharp blade to cut the tape and hold the incised piece of tape with forceps. The opening can be sealed with another strip of tape or a plain 22 mm circle or square glass cover slide and vacuum grease.
- Micro-Bridges can be removed for crystal seeding, mounting, manipulation, and observation.
- Micro-Bridges are designed as disposable devices. It is not recommended to wash and re-use Micro-Bridges.
- Micro-Bridges cannot be siliconized or autoclaved.

SITTING DROP VAPOR DIFFUSION CRYSTALLIZATION

Using Glass Sitting Drop Rods™

The Glass Sitting Drop Rod is a small, solid rod manufactured from clear glass that has a smooth, concave depression in the center of the top region (figure 4). The opposite end of the glass rod is flat and it can hold up to a 100 µl drop. It is inserted into the reservoirs of VDX™ plates to perform a sitting drop vapor diffusion experiment. The Glass Sitting Drop Rod can be secured to the bottom of the plate using vacuum grease or can be left unattached to the bottom of the plate. It can be removed from the plate for crystal manipulation and observation if desired.

1. Pipet 1.0 ml of crystallization reagent into reservoir A1 of a VDX plate. *(Note: Recommended reservoir volume is 0.5 to 1.0 ml; Additional Note: If vacuum grease will be used to secure the Glass Sitting Drop Rod to the plate, apply the grease to the rod and insert the rod prior to pipetting reagent into the reservoir.)*
2. Place a clean (blow the Glass Sitting Drop Rod with clean, dry compressed air before use), siliconized glass rod into the bottom of reservoir A1 such that the concave depression in the Glass Sitting Drop Rod is facing up.
3. Pipet 1 µl of sample into the Glass Sitting Drop Rod in reservoir A1.
4. Pipet 1 µl of reagent from reservoir A1 into the drop in the glass rod A1. *(Note: Some prefer to mix the drop while others do not. Proponents of mixing leave the pipet tip in the drop while gently aspirating and dispensing the drop with the pipet. Mixing ensures a homogenous drop and consistency drop to drop. Proponents of not mixing the drop simply pipet the reagent into the sample with no further mixing.)*
5. Repeat steps 1 through 3 for the remaining 23 reservoirs.
6. Seal the plate with two strips of clear sealing tape or a plain glass cover slide and sealant.

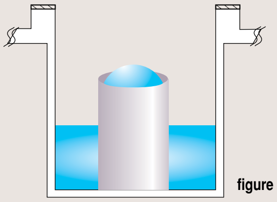

figure 4

Glass Sitting Drop Rods Tips

- To access a drop and/or reservoir of a plate sealed with tape, simply make a circular incision in the tape using the inside of the reservoir as a guide. Use a sharp blade to cut the tape and hold the incised piece of tape with forceps. The opening can be sealed with another strip of tape or a plain 22 mm circle or square glass cover slide and vacuum grease.
- Glass Sitting Drop Rods can be removed for crystal seeding, mounting, manipulation, and observation.
- Siliconize Glass Sitting Drop Rods before use.
- Glass Sitting Drop Rods may be washed and used over and over again. However, if vacuum grease is used to secure the Glass Sitting Drop Rod to the bottom of the reservoir, we wish you good luck in completely removing the grease from the rod.
- Glass Sitting Drop Rods may be autoclaved.

CrystalClear Strips™

CrystalClear Strips consist of a plastic frame and 12 polystyrene strips with a total experiment capacity of 96 per plate. Each strip contains 8 reservoirs and platforms. Typical reservoir volumes are 100 µl. The smooth, concave depression on the platform above the reservoir can hold up to a 10 µl drop. The CrystalClear Strip is sealed with clear sealing tape or film.

Pipet 100 µl of crystallization reagent in each of the 96 reservoirs. Pipet 1 µl of sample into the depression on the ledge of the first reservoir A1. Pipet 1 µl of reagent from reservoir A1 into the drop on the ledge above reservoir A1. Repeat steps 2 and 3 for the remaining 95 reservoirs and wells. Seal the CrystalClear Strips with clear sealing tape or film.

CrystalClear Strips Tips

- The strips are available with and without a concave depression for drop placement.
- While pipetting reagents into the reservoirs, place a clean pipet tip into the first empty reservoir. Move the clean tip ahead one empty reservoir with each reagent addition. This will help one keep track of their pipetting position in the plate.

Sandwich Box™

The Sandwich Box consists of a square polystyrene box, a plastic support, and a siliconized 9 well glass plate. The Sandwich Box is used when a common dehydrant system is desired as well as very large drops. Enormous drops can be pipetted into the siliconized glass wells. The siliconized glass plates offer excellent optics and can be removed from the plastic box to inspect the drop for birefringence without optical interference from plastic. Sandwich Boxes offer unique vapor equilibration kinetics and are very easy to access for crystal seeding, manipulation, and mounting. The plates are often used for heavy atom screening and derivatization and are useful for long-term crystal storage when each well is sealed with a glass slide and vacuum grease.

Open the Sandwich Box and place a plastic support, bottom side facing up into the box. Apply a bead of vacuum grease to the outer top edge of the box or the outer lower edge of the lid. Pour 25 ml of crystallization reagent or common dehydrant into the Sandwich Box. Place the siliconized 9 well glass plate on top of the inverted plastic support. Pipet the sample into one of the nine wells. Add the appropriate crystallization reagent to each drop. Place the cover on the Sandwich Box.

Sandwich Box Tips

- Apply a thin bead of vacuum grease around a single depression of the glass plate and seal the depression with a plain glass cover slide for long term crystal storage.
- Use a siliconized glass depression plate to test a small amount of sample for solubility with various crystallization reagents.

96 Well Plates

The 96 well sitting drop plates offer a variety of drop well configurations and flexibility in a standard microplate footprint. The 8 x 12 reagent wells in 9 mm offset can be filled with automated liquid handling systems or manual, single, and multichannel pipets with a typical reagent fill volume of up to 100 µl. The diversity of the various sample drop wells allow for automated and manual pipetting into a variety of well shapes, volumes and geometries. Materials range from optically clear polystyrene to low birefringent polymers. The plates can be manually or automatically sealed with optically clear sealing tape or film.

CRYSTALLIZATION UNDER OIL

Method

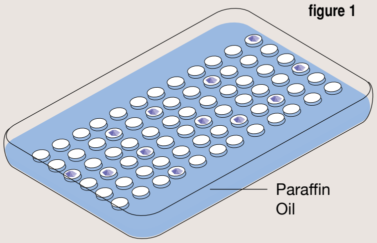
Crystallization under oil is a method where a small drop of sample combined with the crystallization reagent of choice is pipetted under a layer of oil. This is also known as microbatch crystallization.

Oils can also be used as a barrier between the reservoir and the drop in traditional hanging or sitting drop crystallization experiments. This is known as vapor diffusion rate control.

Description of Microbatch

The crystallization of proteins under a thin layer of paraffin oil was originally described by Chayen et al. (Appl. Cryst. 23 (1990) 297). In this technique, a small drop of sample combined with the reagent of choice is pipetted under a small layer of paraffin oil (figure 1). The oil generally used is a mineral oil of branched paraffins in the C20+ range and allows for little to no diffusion of water through the oil. Essentially all of the reagents in a batch or microbatch experiment are present at a specific concentration. Furthermore, there is no significant concentration of either the protein or the reagent within the crystallization drop.

figure 1



Description of Modified Microbatch

D'Arcy et al. (A novel approach to crystallizing proteins under oil, Journal of Crystal Growth 168 (1996) 175-180) modified the microbatch under oil technique by using silicone fluids which are polymeric compounds composed of repeating dimethylsiloxane units -(Si(CH$_3$)$_2$-O-)$_n$-. Using a mixture of 1:1 silicon oil and paraffin oil, also known as Al's Oil, one can perform a microbatch experiment under oil and have diffusion of water from the drop through the oil, hence a microbatch experiment that does allow for concentration of the sample and the reagents in the drop (figure 2).

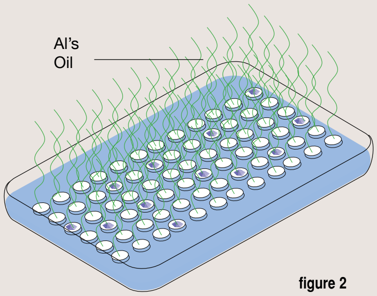


figure 2

Performing Microbatch / Modified Microbatch

Pipet 6 ml of 100% paraffin oil or 6 ml of 1:1 paraffin/silicon oil (Al's Oil) into a 72 Well Microbatch Plate, as shown in figure 1 or 2. *Note: One can also utilize other ratios of paraffin oil and silicon oil to vary the rate of diffusion from the drop (higher % of silicon oil = more rapid diffusion and evaporation).*

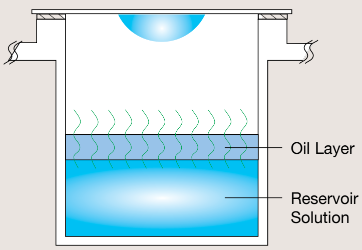
Pipet the sample into the appropriate cone-shaped depression in the microbatch plate followed by addition of the reagent. Typical drop ratios and final drop sizes are 1:1 and 1 to 2 µl. Drops up to 10 µl can be achieved under oil using the microbatch plate. Place plate cover over microbatch plate to prevent dust and debris from entering experiment. The microbatch method can also be performed in round bottom, clear 96 well plates. The oil, reagent, and sample can be mixed quickly and efficiently for fast throughput by using an 8 or 12 channel pipetter.

Description of Vapor Diffusion Rate Control

Chayen (A novel technique to control the rate of vapour diffusion, giving larger protein crystals J. Appl. Cryst 30 (1997) 198-202) has described a technique where oils can be used to vary the rate of vapor diffusion. Using mixtures of paraffin and silicon oil, Chayen reported fewer, larger crystals in the drop.

Using a standard hanging or sitting drop vapor diffusion setup, the drop is first mixed with reservoir solution, thus preventing oil from entering the drop. Then, 200 µl of oil is applied over the reservoir solution (figure 3). The oil acts as a barrier to vapor diffusion between the reservoir and the drop. Using 100% paraffin oil allows limited amount of vapor diffusion to occur, which in turn causes the drop to behave like a batch experiment. The drop will then eventually dry up due to evaporation through the polystyrene plate. Using 100% silicon oil will give results similar to that when no oil is used. When using a mixture of the two oils, the rate of vapor diffusion between the drop and the reservoir may be controlled. The rate of vapor diffusion is also a function of thickness of the oil layer over the reservoir. Chayen evaluated oil volumes between 100 and 700 µl. Oil volumes of 50 to 100 µl resulted in crystals similar to the control without oil. Oil volumes greater than 700 µl have a significant delay in the onset of crystallization, with improved crystal size. Results using hanging drop were more pronounced than sitting drop which may be due to either surface effects or the drop geometry in relation to the reservoir which could influence vapor diffusion kinetics.

figure 3



Performing Vapor Diffusion Rate Control

Prepare a VDX or Cryschem Plate for a sitting or hanging drop vapor diffusion experiment. After the reservoir has been added to the drop, pipet between 200 and 700 µl of a mixture of paraffin/silicon oil onto the reservoir (figure 3). Seal the plate.

Method

Crystallization by dialysis is an easy variation to the typical vapor diffusion method used to grow crystals. In the dialysis method, the sample in question is separated from the "precipitant" by a semi-permeable membrane which allows small molecules such as ions, additives, buffers, and salts to pass but prevents biological macromolecules from crossing the membrane. Equilibration kinetics depend upon the molecular weight cut-off of the dialysis membrane, the precipitant, the ratio of the volume, the concentration of the components inside and outside of the dialysis cell, and the geometry of the cell.

Description

The Dialysis Buttons™ offered by Hampton Research are machined from transparent perspex. The button has a chamber which varies from 5 to 350 µl depending upon which size button one chooses to use. The sample is placed in this chamber so as to create a slight dome of liquid at the top edge of the button. A dialysis membrane (having the appropriate molecular weight cut-off) is placed over the top of the button/sample and is held in place with an O-ring. The O-ring is held in place by a groove in the button. Dialysis Buttons are notoriously tricky to set up since beginners often trap air bubbles between the sample solution and the membrane which impedes dialysis. With a little practice using a golf tee or applicator, one can master the technique. Dialysis Buttons are supplied with O-rings and a golf tee. Dialysis membrane discs and applicators are available separately. The applicator is used to apply the membrane and the O-ring to the buttons.

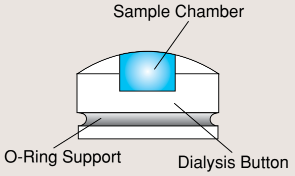

figure 1

Using the Dialysis Button

A typical dialysis experiment is used to take the sample from the presence of a high ionic strength solution to a lower ionic strength solution. However, the technique can just as easily be used to proceed from low ionic strength to a higher ionic strength. This is accomplished by placing the sample in high ionic strength into the Dialysis Button, sealing the button with a dialysis membrane, and placing the sealed button in a solution of ionic strength lower than that inside the button. Salts, ligands, and compounds smaller than the pore size of the dialysis membrane will leave the button as long as their concentration is lower on the opposite side of the membrane. Once the concentration of the diffusible species is the same on both sides of the membrane, the system is in equilibrium.

Cleaning

The buttons can be cleaned with soap and deionized water. Do not clean them with organic solvents as this may turn the perspex opaque.

Practical Example

The following two practicals offer examples of how to set up a dialysis experiment.

Practical 1 - Carboxypeptidase A

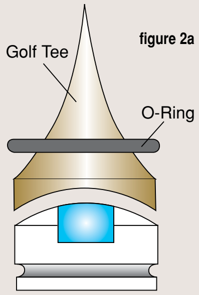

figure 2a

1. Using Carboxypeptidase A (Sigma-Aldrich CO386 or CO261), make an 8 to 20 mg/ml solution of the Carboxypeptidase A in 20 mM Tris HCl pH 7.5, 1.5 M LiCl.
2. Place 100 ul of 10 mg/ml carboxypeptidase in 20 mM Tris HCl, 1.5 M LiCl, pH 7.5 in a 100 ul Dialysis Button. The droplet should have a slight dome shape following the hemispheric edge of the top of the button.

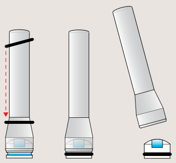

figure 2b

3. Seal the button with dialysis membrane. Using a one inch (2.5 cm) square of dialysis membrane which has equilibrated in water, place the membrane over the top of the button. Place an inverted golf tee on top of the membrane and button. Roll the O-ring down the applicator until the O-ring rolls off onto the edge of the button. Roll the O-ring into the machined groove on the edge of the button. Remove the applicator. There should be no bubbles between the membrane and the sample inside the button. Bubbles will prevent dialysis. Some researchers prefer to use the rubber tipped plunger of a syringe with a modified syringe body to apply the O-ring. Others prefer to use an applicator. Try each and see which method works best.
4. Place 0.9 ml of 20 mM Tris HCl, pH 7.5 in the reservoir of a VDX™ Plate, a Linbro® Plate, or small chamber which can be sealed.
5. Place the Dialysis Button in the well, membrane side up. Be sure the reservoir solution covers the top of the membrane/button. Seal the VDX plate using grease and a cover slide.
6. Observe under a microscope. Crystals will appear within 2 to 3 days. Final concentration of LiCl will be 0.15 M.

Reference for the above protocol: Dr. Jim Pflugrath and Dr. Gary Gilliland, Cold Spring Harbor Laboratory Protein Crystallography Workshop.

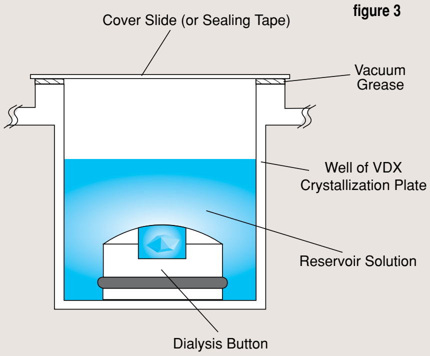

figure 3
Cover Slide (or Sealing Tape)
Vacuum Grease
Well of VDX Crystallization Plate
Reservoir Solution
Dialysis Button

Practical 2 - Lysozyme

1. Prepare 10 mg/ml lysozyme in 50 mM Sodium acetate trihydrate pH 4.5. Filter the solution using a 0.2 micron filter.
2. Fill a 100 µl Dialysis Button with 100 µl of the lysozyme solution as described for the carboxypeptidase practical.
3. Pipet 1 ml of 50 mM Sodium acetate trihydrate buffer into a small (5 ml) beaker.
4. Place the filled button, membrane side up in the beaker.
5. Pipet a small amount of concentrated Sodium chloride into the beaker such that the final concentration of Sodium chloride in the beaker is 0.2 M. Seal the beaker with parafilm and store at room temperature.
6. Increase the concentration of Sodium chloride each day by 0.2 M. Repeat until crystals are observed in the button.

Reference for the above protocol: Crystallization of nucleic acids and proteins, a practical approach. Edited by A. Ducruix and R. Giege, Oxford University Press, 1992.

Considerations

Just as in a vapor diffusion experiment, the path is often as important as the endpoint in a dialysis experiment. The path is the equilibration course which the solution inside and outside the button take toward achieving equilibrium. This course can be changed by manipulating the following:

- Ratio of button volume/reservoir volume
- Button and reservoir components & concentration
- Molecular weight cutoff of dialysis membrane
- Viscosity of solutions
- Plus the usual assortment of crystallization variables including pH, sample concentration, temperature, etc.

Variations of Dialysis

Macrodialysis

The sample is loaded into dialysis tubing of the appropriate molecular weight cutoff and is dialyzed against the appropriate reservoir solution. This method typically requires at least 100 µl of sample and can be performed with liters of sample in large dialysis tubing.

Zeppenzauer Cells

Capillary tubes are closed with dialysis tubing or gel plugs. See Zeppenzauer, M. 1971, Methods In Enzymology, 22, 253.

Microcap Dialysis

The sample is placed in a glass capillary with one end sealed with wax, the other with dialysis membrane. The tube is placed in a microcap/small centrifuge tube filled with the appropriate reagent. See Crystallization of nucleic acids and proteins, a practical approach, Edited by A. Ducruix and R. Giege, Oxford University Press, 1992.

Double Dialysis

This method reduces the rate of equilibration and can provide enhanced control over the crystallization of the sample. Simply put, a Dialysis Button is prepared and placed inside a reservoir sealed with a dialysis membrane, which is in turn placed inside another reservoir. Confused? See Thomas, D.H., et al., 1989, Protein Engineering, 2, 489.

Observing the Experiment

Gently set the plate onto the observation platform. If the platform is smooth and free of protrusions, one may simply slide the plate in the X and Y directions on top of the viewing platform to view each of the drops. Use low magnification to view and center the drop in the field of view. Scan the drops at 20 to 40x magnification. When something suspicious appears, increase the magnification to 80 or 100x for a better view. Scan the entire depth of the drop using the fine focus control of the microscope. Sometimes crystals will form at different depths of the drop because different areas of the drop can equilibrate at different rates. Also, crystals sometimes form at the top of a drop and as the crystal gains mass, it will fall to a lower portion of the drop. Scrutinize everything until you are familiar with the differences between crystals, microcrystals, precipitate, and sweater fuzz. True crystals will feature edges. Precipitate does not have edges. Crystals can appear as needles, blades, walnuts, spherulites, plates, and various geometric shapes. Crystals vary in size anywhere from a barely observable 20 microns to 1 or more mm but most seem to fall in the range of 0.05 to 0.5 mm. Figure 1 shows typical examples of what one might observe in a crystallization experiment.

Diffractable Crystal

Crystals useful for x-ray diffraction analysis are typically single, 0.05 mm or larger, and free of cracks and defects.

Differentiating Between Microcrystals & Precipitate

Microcrystals (less than 0.02 mm) can be difficult to differentiate from precipitate, especially under low power or with a low to medium quality microscope. Differentiate microcrystals from amorphous precipitate by looking for birefringence (light colored shiny spots under a polarizer in dark field mode = crystals). Other tests to differentiate crystals from precipitate include streak seeding, or the use of a small amount (1 µl) of colored, low molecular weight, water soluble dye (crystal violet and methylene blue will often penetrate the solvent channels of macromolecular crystals and color them, where as precipitate will not be colored).

Precipitate can appear as clumps, fine wispy clouds, or anything in between and can range in color from white to yellow, brown, or rust. During screening and very preliminary optimization, one may wish to observe the drops immediately after setup, one day later, and each day thereafter for the first week. Observations may be performed once a week thereafter until the drops turn into a crust of deceased sample and reagent. Never throw plates away until the drop is dead. Why? Most crystallization plates are made from polystyrene which allows for some evaporation over time. Evaporation leads to increased relative supersaturation and over time, may also lead to an increase in crystals. Time also can lead to changes in the protein (denaturation of less stable forms, proteolytic cleavage, and other changes) which might promote crystallization. Take careful notes during observations and be especially conscious of changes that occur between observations. Most crystallization observations are done at room temperature since this is where one will find most microscopes and it is most comfortable.

Cold Experiments

4°C experiments may be observed by moving the microscope into a cold room. Allow time for the microscope to equilibrate to 4°C to prevent fogging of the optics as well as unnecessary temperature transfer from the warm microscope to the cold experiment. Wear a warm jacket with gloves to stay as comfortable as possible in the cold room. Excessive moisture in a cold room can be very destructive to a microscope so check with your maintenance group to keep the cold room as dry as possible. If a cold room is unavailable, one is forced simply to work fast, moving plates from an incubator to the microscope carefully and making rapid, yet thorough observations. Move only one plate at a time and gently close the incubator door between transfers since slamming the door will cause vibrations which can influence crystallization. Cold experiments tend to fog up rapidly, especially if the light source is hot (if no infrared filters or light pipes are used). This is difficult to avoid and is one reason researchers prefer working in cold rooms.

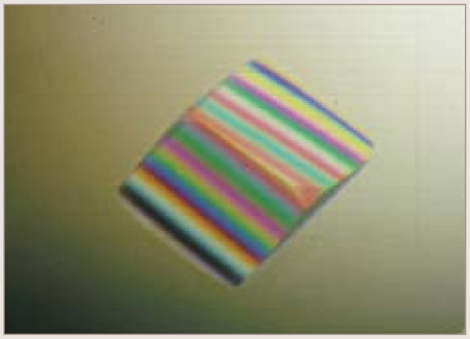
BIREFRINGENCE

The technical mumbo jumbo first. The physical properties of isotropic materials, such as glasses, liquids, and amorphous materials do not depend on direction. However, most properties of a wide variety of crystals (including liquid crystals) do show such variation. This anisotropy of physical properties originates in the anisotropic build-up of the materials (crystal structure). Anisotropy in the optical properties of uniaxial crystals is referred to as either birefringence or dichroism, depending on whether the index of refraction or the absorption coefficient is concerned. Birefringence means that there are two distinct speeds with which light can propagate, depending on the direction of propagation. When a light ray splits into two beams as it passes through a material, the effect is called birefringence (or double refraction) and the material is birefringent. If you look at something through a birefringent material, you'll see double. The word birefringence comes from the Latin bi- (twice) plus refringere (to break up). Thus, the light rays are “broken in two” by a birefringent material. One well-known example of a birefringent medium is crystalline calcite (calcium carbonate). If you look at the world through a clear crystal of calcite (calcium carbonate), you will see double. Place such a crystal on a drawing, and you'll see two overlapping copies of the drawing. The molecular structure of calcite causes double refraction, in which each light ray is split into two rays that emerge from the crystal at slightly different angles. Calcite shows this more clearly than most crystals, but quartz and many other crystalline minerals also split light ray.

Now, the practical interpretation for crystal growers. You might hear the word birefringence used quite often by crystal growers when viewing crystals under a microscope. Here, crystal growers are stretching the definition of the term birefringence to describe the colorful display produced by biological macromolecular crystals when polarized light is passed through the crystal. See figure 1.

figure 1

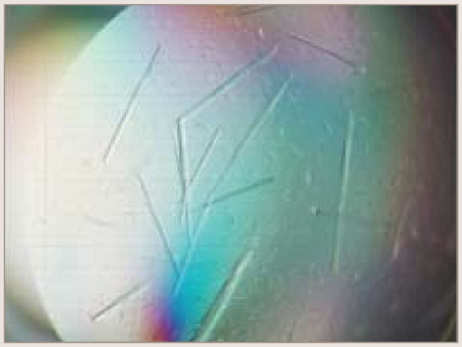


A light microscope with polarizing optics is required to observe birefringence. The following path is a typical setup where light passes from the light source through the first polarizing lens, next the specimen (crystal), then the second polarizing optic, finally the magnifying optics and into your eye. On many typical polarization setups, the second polarizing filter can be rotated while the specimen is stationary. Rotating the polarizing optic without something to rotate the plane of polarized light in the path (i.e. a crystal) will result in one seeing light, dark, light, dark, as the filter is rotated. But if a crystal with birefringent properties (i.e. a biological macromolecular crystal) is positioned in between the two polarizing filters, one will observe changing colors as the polarizing filter is rotated. Specifically, when the polarizing filters are aligned such that the field is dark, a birefringent object (crystal) will glow with color.

Birefringence is one way we can differentiate amorphous precipitate from microcrystals in a drop when viewed under a microscope. Precipitate does not have birefringent properties while most biological macromolecular crystals do.

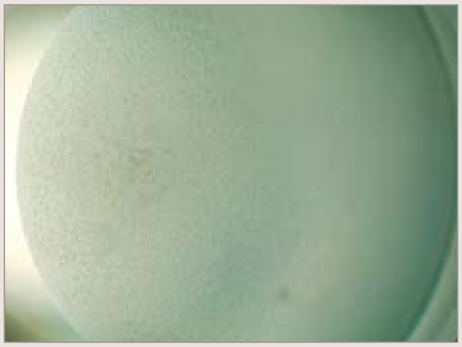
One drawback with using birefringence in today's crystal growth world is that most of the crystallization devices utilized are made from plastic such as polystyrene and polypropylene. These plastics are optically active and can be birefringent. In fact, often times the colors we see displayed in crystals are contributions from the birefringent plastic. See figure 2. However, it is still possible to observe microcrystalline birefringence in the plastic trays, but there is usually a contributory effect from the plates used to grow the crystals. One way to avoid this is to grow crystals in a glass device or at least observe the crystals in a path that is free of birefringent plastics. Some crystallization plates are available in a low birefringent material.

figure 2



Birefringent precipitates will glow, sparkle, or glisten. See figure 3.

figure 3



To test for birefringence, position the polarizers so the field of view is dark WITHOUT the crystallization plate or setup. Place the tray into position on the microscope. If a crystal is birefringent, some of the light passing through the crystal will be rotated and pass through the second (analyzing) polarizing filter. The intensity of the transmitted light will increase and decrease as the crystal or the polarizer is rotated. Remember, birefringence is NOT ALWAYS clearly visible when polystyrene or polypropylene is in the light path (i.e. when you use plastic slides or crystallization plates). However, a birefringent crystal viewed in most plastic trays or plastic cover slides will have a different color than the background (i.e. plastic plate) or foreground (plastic slide). Finally, birefringence is a property of crystals, both biological (proteins, peptides, and nucleic acids) and inorganic crystals (salts). Birefringence is MORE pronounced in inorganic crystals (salt).

A quick comment on what to do with birefringent precipitates. Streak seeding is a common and often successful method of taking advantage of microcrystalline precipitate to grow large single crystals.

SALT OR BIOLOGICAL CRYSTALS?

First of all, before deciding on how to distinguish whether the crystal is inorganic (salt) or biological (protein), take a picture of the crystal before you destroy it or make it disappear.

The most definitive test is to obtain an x-ray diffraction pattern of the crystal. A diffraction pattern of a protein crystal may look like that in figure 1. Want to take a less direct approach? Read on.

The following are ways to differentiate a biological crystal from an inorganic crystal.

1. Dehydration

A biological crystal typically has very significant solvent content and will dehydrate when removed from the drop or when the drop is allowed to evaporate from around the crystal (figure 2). Inorganic crystals typically do not possess large solvent channels and have very little solvent content. Removing an inorganic crystal from the drop or allowing the drop to evaporate from around the crystal will typically not destroy or change the appearance of the inorganic crystal.

2. Physical Manipulation

A biological crystal behaves more like an ordered gel than a hard crystal and will powder, crumble, or break easily when touched with a probe such as a Micro-Tool or needle (figure 3). Inorganic crystals can also break apart, but they require more force and typically make a click or crunching sound when breaking apart under the force of a probe. The inorganic crystals are typically more dense than protein crystals and once broken, the pieces fall quickly and stay put on the bottom of the drop.

3. Birefringence

A biological crystal, unless it is cubic, will be weakly birefringent under cross polarizers (figure 4). Inorganic crystals are typically strongly birefringent under cross polarizers. Some plastic plates and materials are also birefringent so this test is more easily performed and interpreted in an all-glass environment or in a plate made from a low birefringent plastic.

4. Dye absorption

A biological crystal typically has large solvent channels which will accommodate a small molecule dye. Small molecule dyes can travel into these solvent channels and color the crystal (figure 5). Inorganic crystals do not possess such solvent channels and will not absorb the small molecule dye. Dyes are chemicals and have solubility limits. So it is possible that a crystal grown in a reagent of high relative supersaturation may have a reagent concentration that will precipitate or even crystallize the dye. Most dyes under such conditions will crystallize into needles or whiskers and of course be colored. So before adding dye, take a picture or memorize the location of crystals in the drop in case the crystal itself forms crystals. Finally, diluting the drop with dye can sometimes decrease the relative supersaturation in the drop to the point where the biological crystal will dissolve. Once the drop equilibrates again with the reservoir, the crystal may reappear and it may appear in a location different from the original crystal. For dyes, consider Izit (HR4-710) from Hampton Research.

5. Control Experiment

Using the same sample buffer, same reagent, same volumes and same hardware, set an experiment identical to the one that produced the crystals, except leave the sample out of the experiment. Simply replace the sample with the sample buffer. Don't get lazy and use water instead of sample buffer because the sample buffer may be a variable in the formation of the crystals. If a crystal forms that appears visually similar to the original crystal you likely have an inorganic crystal in the original setup.

6. Run a Gel

Collect, wash, and dissolve the crystals. Run the sample on SDS-PAGE. If a band indicates the presence of your sample, there is a high probability that your original crystals are biological.

Hampton Research would like to thank Joe Luft at the Hauptman Woodward Medical Research Institute for his help in putting together the information about inorganic and biological crystals.

pH POINTS TO PONDER

- Never use a pH probe containing AgCl when measuring the pH and/or titrating the pH of Tris and Tris HCl buffers since the AgCl will complex with the Tris which can lead to erroneous pH readings. Use a Tris-compatible pH probe when adjusting the pH of Tris buffers.
- Follow the manufacturer's recommended use and maintenance instructions to keep the pH probe accurate and precise.
- pH measurements are only as good as the probe.
- Glass electrode probes are more precise and accurate than gel-filled plastic probes.
- Calibrate pH probes each and every day. Refresh calibration standard solutions frequently to avoid contamination and evaporation.
- A two-point calibration with the "pH to be measured" sandwiched between the calibration points is better than a single or triple point calibration.
- Bacterial contamination of pH standards, storage solution, and water can cause pH fluctuations in reagents.

CRYSTAL GROWTH VIA pH RELAXATION

Try the following if sample solubility is pH dependent. Determine a pH and salt concentration where the protein is insoluble. A simple way to do this, if sample supply is limited, is to review old drops and look for those which contain precipitate. Review the data and select the reagent, reagent concentration, and pH most often associated with precipitate. Or, if sample is abundant, using a microscope, a microscope slide, or cover slide, empirically perform solubility tests by adding 1 µl of protein to 1 µl of buffer (and/or precipitant) and watch the drop for the formation of precipitate within a minute or so (not too long or the drop will evaporate and you will always observe precipitate!). Once reagent and pH points have been determined to promote a sample solubility minima, set hanging or sitting drop vapor diffusion experiments with a smattering of the solubility minima conditions. Once the sample has precipitated, add acetic acid (acidic) or ammonium hydroxide (basic) to the drop (try 1 µl of 0.1 M stock and adjust the amount and/or concentration of the stock accordingly) until the precipitate is redissolved. Seal the reservoir. The addition of the acid or the base will, in most experiments, solubilize the precipitate. Since acetic acid and ammonium hydroxide are volatile, the acidic/basic reagent will leave the drop. As the acidic/basic reagent leaves the drop, the pH of the drop will relax to approximately the original pH prior to the addition of the acidic/basic reagent. As the relaxation approaches the original pH, the protein will approach a point of solubility minima and here is when there is the chance for crystallization to occur. Variables to consider when refining the pH relaxation technique include initial pH, buffer concentration, buffer type, precipitant type, precipitant concentration, concentration and volume of acetic acid/ammonium hydroxide added to the drop, reservoir volume, and drop volume. One can also incorporate additives (organic solvents, chaotropes, detergents, ions, salts, etc.) into the procedure to evaluate the effect of the additive on sample-sample and sample-solvent interactions. Sound tedious? Well, it's not as bad as it sounds. Approach the technique as both a crystallization experiment and a crude solubility measurement. If no crystals are grown using the method, all is not lost. One has at least obtained a great deal of pH and reagent dependent solubility data which can be used to design additional crystallization experiments. What should one do with the old experiments full of precipitate and no crystals? Move the plates to warmer and then cooler temperatures. Note changes in sample solubility. See a difference? Consider temperature relaxation as another crystallization method.

CRYSTALLIZATION POLLING BOOTH

What temperatures do you routinely use for crystallization?

Answer	Percentage
4°C only	3%
25°C only	43%
4°C and 25°C only	33%
4°C and 25°C and other temperatures	21%

How important is it to keep your chosen crystallization temperature constant during the entire crystallization experiment (e.g. during crystal growth and crystal inspection)?

Answer	Percentage
Very important	45%
Important	35%
Neither important nor unimportant	7%
Slightly important	8%
Not important at all	4%

What crystallization method do you use most often for crystal optimization?

Answer	Percentage
Hanging Drop Vapor Diffusion	66%
Sitting Drop Vapor Diffusion	31%
Microbatch	3%
Free Interface Diffusion	0%
Dialysis	0%

What crystallization method do you use most often for screening?

Answer	Percentage
Hanging Drop Vapor Diffusion	36%
Sitting Drop Vapor Diffusion	58%
Microbatch	5%
Free Interface Diffusion	0.5%
Dialysis	0.5%

Based on your own experience, if your protein has a His tag, do you cleave it or leave it when you screen for crystallization conditions?

Answer	Percentage
Cleave it (remove His tag) and screen	26%
Leave tag intact and screen	15%
Leave it & screen. No xtals, cleave & screen.	59%

Cryobuffer

We've had good success using the well solution directly as the foundation of a cryobuffer in several situations where crystals cannot be grown directly in the presence of cryoprotectant, and where crystals don't tolerate transfer to artificial mother liquors. The basic protocol is as follows:

1. Remove 100 µl of the well solution after crystals have grown.
2. Split this sample into two 50 µl aliquots.
3. Add 7.5 mg of Dextrose (glucose) to the first aliquot and 15 mg of Dextrose to the second. Dissolve by gently pipetting with a wide-bore tip. This will give two sequential well solutions that now contain 15% and 30% w/v Dextrose. If all the dextrose won't go into the second aliquot, spin hard and remove the supernatant.
4. Transfer the crystal to aliquot 1, equilibrate for 3 minutes, then to aliquot number 2, then freeze.

We've had a few crystals that routinely crack or blow up when transferred to artificial mother liquor that behave well when transferred to well solution plus glucose. We assume that there is some aspect of the crystal drop (pH, ionic tension, precipitant concentration) that is more effectively reproduced within the well than by separately prepared mother liquors.

The nice thing about the protocol above is that you don't get much of a volume increase when dry dextrose is dissolved in the well solution, so the components in the solution are not diluted.

Finally, if you don't get a really good freeze, you can try to add about 5% v/v Glycerol to aliquot 2 in addition to the 30% w/v Dextrose.

Thank you Barry Stoddard for sharing this tip.

Cryo Tip

When adding glycerol to crystallization experiments for cryogenic data collection, remember that some proteins are more soluble in glycerol and one might have to increase the concentration of the primary precipitant (Example: Increase Ammonium sulfate from 2.0 M to 2.1 M or 2.2 M in the presence of 20% v/v Glycerol).

Cryo-Soaking Method

Eom et al. have reported improved diffraction using a novel cryo-soaking method. Crystals were grown using the following condition: 1.8 M Ammonium sulfate, 0.1 M Sodium citrate pH 5.1 (hanging drop, 0.5 ml reservoir). To improve diffraction quality, the crystals were sequentially transferred to cryosolvents containing 5 to 25% v/v Glycerol in five steps (5, 10, 15, 20, and 25%). Equilibration at each step was 30 seconds. Note that the cryoprotectant (glycerol) also contains the mother liquor used to grow the crystals. Equilibration at each step was 30 seconds. After the final transfer, the crystals were equilibrated for 30 minutes. The cryosolvent containing the crystal(s) was then air dried until Ammonium sulfate crystals began to appear. The authors report this took about 20 minutes at room temperature. Diffraction resolution using the novel cryo-soaking method improved from 3 angstrom to 2.2 angstrom. (Editors Note: Yet another case of crystal dehydration?)

Crystal Annealing

Flash-cooling crystals can sometimes increase the mosaicity of biological macromolecular crystals. In some cases, macromolecular crystal annealing can reduce the mosaicity of flash-cooled crystals without affecting molecular structure. Crystal annealing involves cycling a flash-cooled crystal to room temperature and then back to cryogenic temperature. The procedure can also be applied to sometimes restore diffraction from flash-cooled crystals that were not properly handled to and from cryogenic storage. Crystal annealing does not seem to improve a poorly diffracting crystal suffering from molecular disorder. The essential features of the crystal annealing procedure are the following: The crystal is first flash-cooled. The crystal is removed from the cryostream and quickly transferred to a drop of cryoprotectant at crystal growth temperature and allowed to remain in the drop for at least three minutes. The drop should be covered to prevent evaporation. Finally, the crystal is remounted on a loop and flash-cooled.

Halides for Phasing Proteins

In the publication, "Novel approach to phasing proteins: derivatization by short cryo-soaking with halides", Dauter et al. described the procedure with four different proteins including lysozyme, RNAase A, subtilisin, and xylanase. Hey! Congratulations for taking the time to test beyond lysozyme! We wish more folks would take the time to test novel crystallization "discoveries" with more than just lysozyme! Anyway, Sodium iodide or Sodium bromide was added to the crystallization reagent and cryoprotectant mixture for the derivatization. It was noted that 1.0 M Sodium bromide did not seem to affect the quality and diffracting power of the tested crystals. 1.0 M Potassium iodide did mess with the crystallization of lysozyme and xylanase so the Potassium iodide concentration was reduced to 0.35 and 0.5 M for these two proteins (CrystalNews Editor Note: Both lysozyme and xylanase were crystallized in high salt where the other two proteins were crystallized in MPD and PEG. So it seems one might need to adjust the NaBr or KI concentration for high salt crystallizations and perhaps not too much for polymer or non-volatile organic crystallizations. Who knows? More results needed for a consensus). Crystals were transferred to the halide laced mother liquor for 15 to 45 seconds. Crystals were then flash-cooled (you are welcome Sean) for data collection. A fifth protein, in fact, a new protein to be described in a future publication was also successfully tested with this novel protocol.

For more details about the identification of anamolous sites, the phasing, and application to an unknown structure, see the following reference about quick cryo-soaking with halides as a possible alternative method for phasing protein crystal structures.

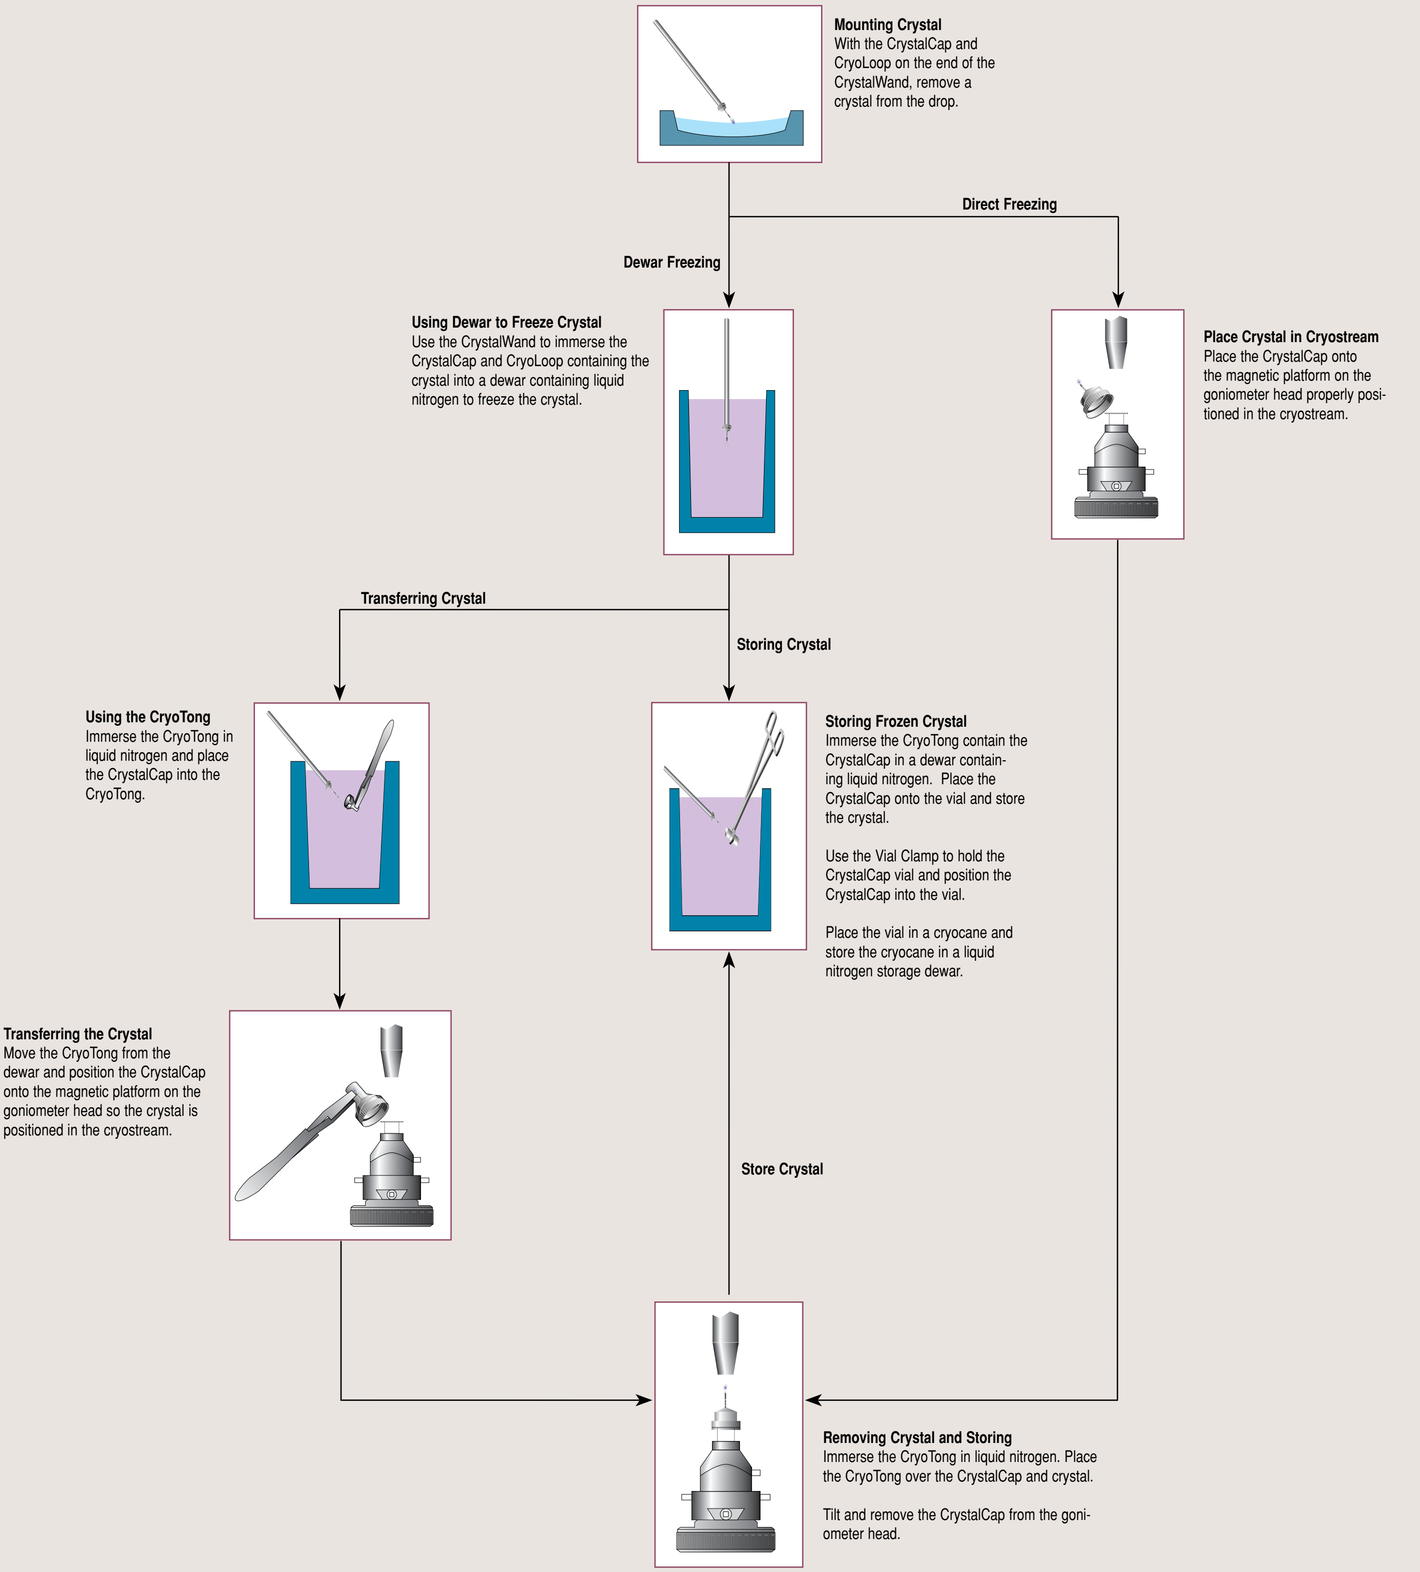
Solutions for Crystal Growth

HOW TO: CRYOCRYSTALLOGRAPHY AND THE CRYSTALCAP SYSTEM

FLOWCHART FOR CRYO COOLING OF CRYSTALS



Mounting Crystal
With the CrystalCap and CryoLoop on the end of the CrystalWand, remove a crystal from the drop.

Using Dewar to Freeze Crystal
Use the CrystalWand to immerse the CrystalCap and CryoLoop containing the crystal into a dewar containing liquid nitrogen to freeze the crystal.

Place Crystal in Cryostream
Place the CrystalCap onto the magnetic platform on the goniometer head properly positioned in the cryostream.

Using the CryoTong
Immerse the CryoTong in liquid nitrogen and place the CrystalCap into the CryoTong.

Storing Frozen Crystal
Immerse the CryoTong contain the CrystalCap in a dewar containing liquid nitrogen. Place the CrystalCap onto the vial and store the crystal.

Use the Vial Clamp to hold the CrystalCap vial and position the CrystalCap into the vial.

Place the vial in a cryocane and store the cryocane in a liquid nitrogen storage dewar.

Transferring the Crystal
Move the CryoTong from the dewar and position the CrystalCap onto the magnetic platform on the goniometer head so the crystal is positioned in the cryostream.

Removing Crystal and Storing
Immerse the CryoTong in liquid nitrogen. Place the CryoTong over the CrystalCap and crystal.

Tilt and remove the CrystalCap from the goniometer head.

USING HALIDES FOR PHASING MOLECULAR STRUCTURES

Preliminary research shows that bromide (as well as iodide) can diffuse into protein crystals when soaked with the appropriate solution and can successfully be used for phasing.[1] Halide soaked crystals can be used for MAD, as well as multiple or single isomorphous replacement with anomalous scattering or for single anomalous diffraction. The procedure has been termed "Halide Cryosoaking" by Dauter and Dauter.[1] In simplest terms, the procedure involves dipping the crystal for a short period of time into a cryoprotectant solution that contains a significant concentration of halide salt. Although no single recipe will suffice for all proteins since each crystal has a unique crystallization recipe and will require different cryoprotectant cocktails, there are some general suggestions to follow at this time. First, there are currently more successful examples using bromide than iodide. The soak time is approximately 10 to 20 seconds. Longer soaks have not lead to more incorporation of halide ions for the examples to date. The concentration range of sodium bromide for soaking is approximately 0.25 to 1 M. Higher concentrations of halide ions may lead to more sites with higher occupancies and increased phasing power. Factors influencing the success of the procedure include the resolution and quality of the x-ray diffraction data, crystal symmetry, packing density, and pseudo-symmetric arrangements of molecules.

Tips for successful Halide cryosoak include:

1. Initially, preserve the formulation of the crystallization reagent used to grow the crystal as well as the formulation for a successful cryosoak and then add the halide salt. In other words, leave everything constant and add the halide salt.
2. If the crystallization reagent contains salt, try substituting the halide salt, especially if the salt is Sodium chloride.
3. High concentrations of the halide salt can serve as a cryoprotectant without the addition of other traditional cryoprotectants (Glycerol, MPD, sucrose).
4. Experiment with soak conditions. Vary the concentration of the original reagents, the concentration of the halide salt, and the soak time.

Examples of successful crystallization reagents optimized for halide cryosoaking:

Original Condition (Black) Halide Cryosoak Condition (Blue)

1.0 M Ammonium sulfate, 5 mM guanidine, 10% Glycerol, 0.1 M Sodium citrate pH 3.3[3]

1.0 M Ammonium sulfate, 5 mM guanidine, 18% Glycerol, 0.1 M Sodium citrate pH 3.3, 1 M Sodium bromide[3]

1.4 M Lithium sulfate, 0.1 M Tris pH 7.5[3]

1.2 M Lithium sulfate, 0.1 M Tris pH 7.5, 1 M Sodium bromide, 14% Glycerol[3]

1.0 M Sodium chloride, 0.1 M Sodium acetate pH 4.7[2]

0.1 M Sodium acetate pH 4.7, 1.0 M Sodium bromide, 30% Glycerol[2]

50% MPD, 0.1 M Sodium acetate pH 5.4[2]

50% MPD, 0.1 M Sodium acetate pH 5.4, 1.0 M Sodium bromide[2]

12% PEG 4,000, 0.1 M Citrate, 1.0 M Sodium chloride, 10 mM Calcium chloride, pH 6.0[2]

12% PEG 4,000, 10 mM Citrate, 10 mM Calcium chloride, 25% Glycerol, 1.0 M Sodium bromide[2]

10% Ammonium sulfate, 0.1 M TRIS HCl pH 7.4[2]

10% Ammonium sulfate, 0.1 M TRIS HCl pH 7.4, 25% Glycerol, 1.0 M Sodium bromide[2]

MICROSEEDING

Background

A crystallization experiment typically begins with the sample in a stabilizing solution of water and a buffer, salt, reducing agent, ligand, or other reagent. Prior to mixing the sample with crystallization reagent, this sample solution is undersaturated with respect to the macromolecule in question (sample). In an undersaturated sample solution, no crystals can nucleate, nor can crystals grow from seeds. Upon addition of a crystallization reagent, the relative supersaturation of the sample is increased. Assuming the crystallization reagent decreases the solubility of the sample to increase the relative supersaturation, three events can take place. In the first stage of supersaturation, the metastable zone, spontaneous homogenous nucleation cannot occur, but crystal growth from seeds can occur. Moving further into supersaturation, the labile zone, spontaneous homogeneous nucleation and crystal growth can occur. Further into supersaturation, the precipitation zone, precipitation of the sample from solution occurs. See figure 1 below.

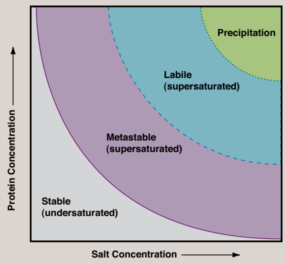

figure 1

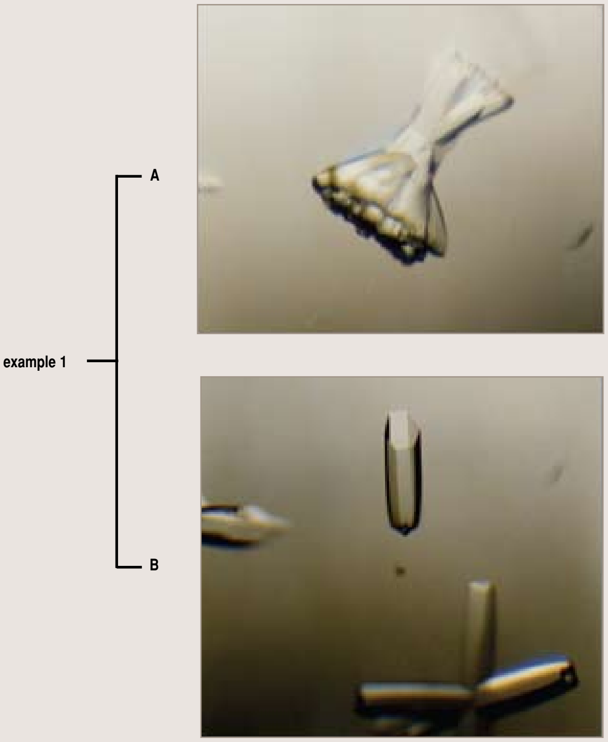
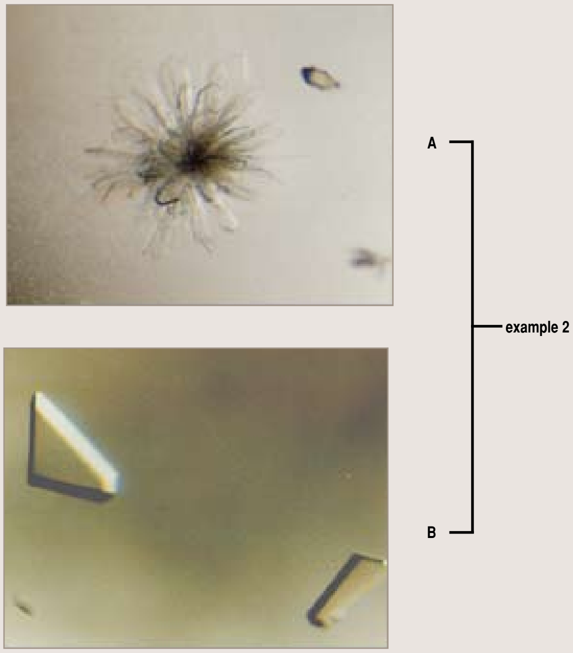
The diagram is divided into 4 zones:

1. **Stable:** undersaturated where crystallization is not possible.
2. **Metastable:** supersaturated where nuclei cannot form but crystals from seeds can grow.
3. **Labile:** supersaturated where crystallization can occur.
4. **Precipitation**



Seeding

Seeding allows one to grow crystals in the metastable zone. Why would one want to do this? For control, reproducibility, and to improve the likelihood of a successful crystallization experiment. In the metastable zone, crystals can grow from seeds but cannot spontaneously nucleate. By placing a seed or solution of seeds in a drop which is saturated to this zone, one can use the seeds to grow larger single crystals. By controlling the number of seeds introduced into the zone drop, one can control the number of crystals grown. It is not practically possible to measure and know the number of seeds introduced to a drop, but by performing serial dilutions from a concentrated seed stock, one can control the number of crystals grown in the drop.



Seeding Examples

Example 1: (A) Initial crystals of the catalytic domain of CheB methyltransferase were grown from Crystal Screen 2™, reagent 42. (B) Microseeds were taken from (A) to grow diffraction quality crystals.

Example 2: (A) Initial crystals of CheR methyltransferase were grown producing platelet clustered crystals. (B) Microseeds were taken from (A) to grow quality 3-dimensional crystals.

Thank you Ann West and Snezana Djordjevic for your examples of microseeding.

DETERGENTS AT WORK

The image below is a view of the crystal packing of ß-lactamase. The image demonstrates the detergent molecule linking SHV-1 molecules in the crystal lattice. The detergent binding to the ß-lactamase is CYMAL®-6. It appears as though the well-ordered detergent molecules are linking protein molecules in the crystal lattice. The hydrophobic tail of the detergent is buried in the protein and the hydrophilic head is hydrogen bonded with a neighboring molecule.

ß-lactamase resisted producing any decent crystals until the detergents CYMAL®-5 and CYMAL®-6 were included in the crystallization drop. The crystals were grown in a relatively low ionic strength environment (15% w/v PEG 6,000, 50 mM HEPES pH 7.0, and detergent) via sitting drop vapor diffusion.

The crystals and the structure demonstrate the efficacy of detergents as additives to improve crystallization of soluble proteins and bring to light the molecular linking capabilities that small molecules can have in biological macromolecular crystals.

CYMAL®-5 and CYMAL®-6 are part of the Hampton Research Detergent Screen.

CRYSTALLIZATION EXPERIMENTS ON THE PHOTOSYSTEM II REACTION CENTER FROM PISUM SATIVUM

Submitted by Ivana Kuta Smatanova, University of South Bohemia, Photosynthesis Research Center and Laboratory of Biomembranes, Branisovska 31, CZ-370 05 Ceske Budejovice, Czech Republic

Crystallization trials have been performed in Cryschem™ Plates for sitting drops and in capillary tubes at 277K or 289K. 15-mg/ml (1.3 mg/ml chlorophyll a) protein has been mixed with different type of detergents and additives used in the crystallization experiments. We have either used the Hampton Research MembFac kit for membrane protein screening or solutions prepared in our own lab. 50 commercial solutions and 50 different kind of detergents have been available for experiments. According to the published information about a crystallization of photosynthetic reaction center core complexes we have used solutions containing PEG as precipitant. Concerning detergents we have proceeded in accordance with literature data and up to this day we have tried 15 different detergents, detergents with different alkyl chain length and mixtures of detergent as well. Processes inside the drops have been observed during the period of 2-4 weeks at 289K and 4-6 weeks at 277K. The major part of drops contained precipitates, separated phases or segregated carotenoids in various forms. We have already found for crystallization experiments acceptable pH rate around 7.00 (±0.50), the precipitant PEG 4000 or PEG 6000 (in the case of using a commercial solutions without PEGs, we have observed the clear drops without precipitate or other formations). For detergents, in the presence of 1-heptyl-ß-D-glucoside, 1-octyl-ß-D-glucoside, 1-nonyl-ß-D-glucoside and their thio forms such as heptyl-ß-D-thioglucoside and 1-octyl-ß-D-thioglucoside, different type of carotenoid formations are separated from the protein samples. We have also performed crystallization experiments either in the absence or in the presence of additional amphiphiles (heptanetriol) that has been used to modify detergent characteristics and to facilitate membrane protein crystallization.[1] Nowadays crystallization experiments are still in the progress; we have tried to use new kind of detergents and their mixtures and new crystallization conditions as well.

PROTEIN CRYSTALLIZATION RECIPES

The following crystallization recipes can be useful for teaching and practicing protein crystallization or for fooling your PI into thinking you have grown huge crystals of that impossible-to-crystallize protein.

Lysozyme

Protein source: Hampton Research HR7-108 or HR7-110
Worthington Biochemical Corporation
Sigma-Aldrich
Recommended concentration: 20 to 100 mg/ml
Sample Buffer: 0.1 M Sodium acetate pH 4.6
Crystallization reagent: 8% w/v Sodium chloride, 0.1 M Sodium acetate pH 4.6
10% w/v Sodium chloride, 0.1 M Sodium acetate pH 4.6, 10% v/v Glycerol
Additional Reagents: Hampton Research Index screen reagents 8, 22, 28, 31, 34, 40, 58, 59, 69, 86, 88 and Hampton Research Grid Screen Sodium Chloride reagents
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of lysozyme with reagent, incubate at 4°C or room temperature

Lysozyme crystals in 15 minutes

Recommended concentration: 100 mg/ml
Sample Buffer: 0.1 M Sodium acetate pH 4.6
Crystallization reagent: 30% w/v PEG MME 5,000, 1.0 M Sodium chloride, 0.05 M Sodium acetate trihydrate pH 4.6 (Hampton Research HR2-805)
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of lysozyme with reagent, incubate at 4°C or room temperature

Thaumatin

Protein source: Worthington Biochemical Corporation or Sigma-Aldrich
Recommended concentration: 20 to 40 mg/ml
Sample buffer: DI water, 25 mM BIS-TRIS propane or Imidazole pH 6.5
Crystallization reagent: 1.0 M Potassium sodium tartrate
Additional reagents: Hampton Research Index screen reagents 26, 31, 78, 86
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Glucose isomerase

Protein Source: Hampton Research HR7-100 or HR7-102
Recommended concentration: 10 to 40 mg/ml
Sample buffer: 10 mM HEPES, 1 mM Magnesium chloride hexahydrate
Crystallization reagent:

- 1.5 - 2.5 M Ammonium sulfate pH 6.0 - 9.0
- 10 - 15 % w/v PEG 4,000 - 8,000, 0.2 M salt *, 6.0 - 9.0
- 0.6 - 1.0 M Sodium citrate tribasic dihydrate, pH 6.0 - 8.0
- 0.1 - 0.3 M Magnesium formate dihydrate
- 1.0 M Sodium formate, pH 5.0 - 7.0
- 10 - 20 % v/v MPD, 0.2 M salt *, pH 6.0 - 9.0
- 10 - 20 % v/v PEG 400, 0.2 M salt *, pH 6.0 - 9.0
- 10 - 20 % 2-Propanol, 0.2 M salt *, pH 6.0 - 9.0

* Ammonium sulfate, Magnesium acetate, Magnesium chloride, Calcium acetate and other salts
Additional reagents: Hampton Research Index screen reagents including but not limited to 4, 5, 14, 48, 49, 67, 92
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C

Glucose isomerase for cryo

Special thanks to Laurie Betts for the the cryo work and data!
Protein Source: Hampton Research HR7-100 or HR7-102
Recommended concentration 20 to 30 mg/ml
Sample buffer 10 mM HEPES, 1 mM Magnesium chloride hexahydrate
Crystallization reagent: 30% v/v 2-Methyl-2,4-pentanediol, 0.1 M Sodium Cacodylate pH 6.5, 0.2 M Magnesium Acetate tetrahydrate (Crystal Screen Cryo reagent 21) or 30% v/v Polyethylene Glycol 400, 0.1 M HEPES - Na pH 7.5, 0.2 M Magnesium Chloride hexahydrate (Crystal Screen Cryo reagent 23)
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Method: Mix equal amounts of Glucose isomerase and reagent. Mount crystal in CryoLoop. Swish mounted crystal through reservoir to increase MPD or PEG 400 concentration in crystal to decrease mosaicity. No swish for more mosaicity. Crystal can diffract to 1.6 Angstrom, indexes in I-centered orthorhombic with a=92.7 b=97.4 c=102.7. Mosaicity is about 0.5 to 0.6.

Alpha Lactalbumin

Protein source: Sigma-Aldrich
Recommended concentration 10 to 20 mg/ml
Sample buffer: 10 mM TRIS hydrochloride pH 8.5
Crystallization reagent: 30% w/v Polyethylene glycol 3,350, 0.1 M TRIS hydrochloride pH 8.5, 0.2 M Lithium sulfate
Additional reagents: Hampton Research Index screen reagent including but not limited to
4, 5, 6, 74
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Catalase

Protein source: Worthington Biochemical Corporation or Sigma-Aldrich
Recommended concentration: 10 to 20 mg/ml
Sample buffer: 10 mM HEPES pH 7.0
Crystallization reagent: 20% w/v Polyethylene glycol 3,350, 0.1 M HEPES pH 7.0
Additional reagents: Hampton Research Index screen reagents including but not limited to 39, 55, 63, 64, 88, 89
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Ribonuclease S
Protein source: Sigma-Aldrich
Recommended concentration: 40 mg/m
Sample buffer: 10 mM HEPES pH 7.0
Crystallization reagent: 30% Polyethylene glycol 4,000, 0.1 M Sodium citrate tribasic dihydrate pH 5.6, 0.2 M Ammonium acetate
Additional reagents: Hampton Research Crystal Screen reagent including but not limited to 9, 20
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Proteinase K
Protein source: Sigma-Aldrich
Recommended concentration: 20 mg/ml
Sample buffer: 10 mM HEPES pH 7.0
Crystallization reagent: 0.4 M Potassium sodium tartrate tetrahydrate
Additional reagents: Hampton Research Crystal Screen reagent including but not limited to 2, 3, 4, 6, 7, 9, 10, 11, 15, 16, 17, 18, 20, 22, 25, 28, 29, 30, 31, 32, 33, 34, 35, 36, 38, 39, 40, 41, 42, 44, 45, 46, 47, 48, 49, 50
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Trypsin (bovine pancreas)
Protein source: Worthington Biochemical Corporation or Sigma-Aldrich
Recommended concentration: 15 to 60 mg/ml
Sample buffer: 10 mM Calcium chloride, 10 mg/ml Benzamidine hydrochloride, 20 mM HEPES pH 7.0
Crystallization reagent: 4% w/v Polyethylene glycol 4,000, 0.2 M Lithium sulfate monohydrate, 0.1 M HEPES pH 7.0, 15% v/v Ethylene glycol
Additional reagents: Hampton Research Crystal Screen reagents including but not limited to 4, 15, 16, 20, 28, 30, 31
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Ferritin
Protein source: Sigma-Aldrich
Recommended concentration: 20 mg/ml
Sample buffer: 10 mM HEPES pH 7.0
Crystallization reagent: 0.8 Ms Ammonium sulfate, 0.1 M HEPES pH 7.5, 60 mM Cadmium sulfate
Additional reagents: Crystal Screen 2 reagents 12, 34 and Index screen reagent 64 and PEG/Ion 2 reagent 42 and PEGRx 2 reagent 20
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Xylanase
Protein source: Hampton Research HR7-104, HR7-106
Recommended concentration: 3 to 20 mg/ml
Sample buffer: 0.09 M Sodium potassium phosphate pH 7, 21% v/v Glycerol
Crystallization reagent: 1.0 M Sodium potassium phosphate pH 7
Additional reagents: Quik Screen reagents A5, B5, C5, D5, A6, B6, C6, D6
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

Lipase B
Protein source: Hampton Research HR7-099
Recommended concentration: 10 to 100 mg/ml
Sample buffer: Deionized water or 10 mM Sodium acetate pH 4.6
Crystallization reagent: 1.0 M Sodium potassium phosphate pH 7
Additional reagents: Quik Screen reagents A5, B5, C5, D5, A6, B6, C6, D6
Method: Hanging or sitting drop vapor diffusion, microbatch, free interface diffusion
Procedure: Mix equal amounts of protein with reagent, incubate at 4°C or room temperature

TEMPERATURE AS A CRYSTALLIZATION VARIABLE

Temperature and Crystallization

Temperature can be a significant variable in biological macromolecule and small molecule crystallization.(1-5) Temperature often influences nucleation and crystal growth by manipulating the solubility and supersaturation of the sample. Temperature has also been shown to be an important variable with phase separation in detergent solutions during membrane protein crystallization.[7]

Control and manipulation of temperature during the screening, optimization and production of crystals is a prerequisite for successful and reproducible crystal growth of proteins with temperature dependent solubility. Christopher et al.,[5] testing 30 randomly chosen proteins, found 86% demonstrated a temperature dependent solubility and suggested that temperature induced crystallization could be a generally useful technique. Temperature was shown to affect quantity, size, and quality of the crystals, as well as sample solubility and preliminary crystallization data.

One advantage of temperature is that it provides precise, quick, and reversible control of relative supersaturation. Using temperature, in addition to standard crystallization variables such as pH, reagent composition and concentration, and sample concentration, can increase the probability of producing crystals as well as uncover new crystallization conditions for a sample. Additional crystallization conditions may uncover reagent formulations more amicable to heavy atom derivatization, cryoprotection, and optimization or at least offer options. Temperature is amenable to control and can be used to carefully manipulate crystal nucleation and growth. This control can also be used to etch or partially dissolve the crystal and then grow it back in an attempt to improve size, morphology, and quality or assist with seeding. Temperature control is noninvasive and can manipulate sample solubility and crystallization with altering reagent formulation.

Typically, crystallization screens and experiments are performed at room temperature and possibly 4°C. A reasonable range of temperature to screen and optimize for protein crystallization is 4 to 37°C and some proteins have been crystallized at 60°C (glucagon and choriomammotropin). Temperature incubations above room temperature should be monitored closely for evaporation from the drop and reservoir. A 2 µl hanging drop vapor diffusion experiment at 37 °C can evaporate in as little as 48 hours depending upon the plate and the quality of seal. Microbatch under Paraffin Oil can minimize evaporation problems. In the case of room temperature incubations, temperature control and stability are often minimal since the experiments may be left in the open room. In an open room, temperature fluctuations may be significant, especially over a 24 hour period and on weekends when thermostatic control of the room environment can fluctuate 10 degrees or more. Incubation at 4°C and other temperatures are often more stable since the incubation is performed in some type of incubator. Another source of temperature fluctuation occurs while viewing experiments. The light microscope is a heat source and extended viewing can significantly alter the temperature of small drops. Quick, efficient viewing can minimize temperature changes. Also, remember to turn off the light source when leaving plates on the stage in one position for more than a few seconds.

While controlled temperature can be important for consistent results, temperature fluctuation can be useful in obtaining high quality crystals by screening a larger range of crystallization conditions.[8] For a sample with temperature dependent solubility, changes in temperature can equate to changes in a crystallization reagent condition. Hence, a sparse matrix screen takes on a new dimension when screened at multiple temperatures, or ramped over several different temperatures over a period of time.

How does one test for the effect of temperature and temperature dependent solubility without consuming a lot of sample? One solution is to set a single crystallization screen at one temperature, allow the experiment to incubate for a week, record the results, and then move the plate to another temperature. Allow the experiment to incubate for a few days to a week at the new temperature and record the results. If one notices changes is solubility (i.e. clear drop turning to precipitate, or precipitate turning to clear drops) between the two temperatures, then the sample has temperature dependent solubility and temperature should be explored as a crystallization variable.

Temperature gradients can be used for screening and optimization of proteins with temperature dependent solubility. For screening, set the experiment at one temperature, allow it to equilibrate, and then slowly change the temperature to a second temperature. In general, ramp the temperature so that the sample is exposed to an increase in relative supersaturation as the temperature changes over time. In other words, ramp from high to low temperature if the sample is more soluble at high temperatures. This can be accomplished using a programmable temperature incubator. A temperature gradient or ramp, allows one to slowly approach temperatures where a sample may have a decrease in solubility with a corresponding increase in relative supersaturation. Published examples of temperature gradient or temperature ramp crystallization include elastase9 (25 to 20°C gradient), alpha-amylase10 (25 to 12°C gradient), and insulin11 (50 to 25°C gradient).

To demonstrate how screening temperature could affect and enhance the results obtained from a preliminary crystallization screen, a temperature incubator was used to screen four different temperatures. Using Glucose isomerase and Crystal Screen™, sitting drop vapor diffusion experiments were set using Cryschem™ plates at 4, 15, 25, and 37°C. Drops were observed daily and the results were quite interesting. Glucose Isomerase crystallized in 19 conditions at 25°C, 23 conditions at 15°C, 28 conditions at 4°C, and 12 conditions at 37°C. A similar approach with Trypsin, yielded crystals in 8 conditions at 15°C, 4 conditions at 25°C, and 7 conditions at 32°C. In the case of Trypsin, a single set of Cryschem plates were set and then simply moved from one temperature to another over a period of one week, scoring results before each temperature change.

Temperature Tips

- For proteins with "normal" solubility, in high salt they will be more soluble at cold than at warm temperatures.

- For proteins with "normal" solubility, in low salt they will be more soluble at warm than at cold temperatures.

continued next page....

- For proteins with "normal" solubility, they will precipitate or crystallize from lower concentration of PEG, MPD, or organic solvent more slowly at low than at high temperatures.

- Temperature effects can be more pronounced in low ionic strength reagent conditions.

- Do not use the appearance or non-appearance of crystals at various temperatures to gauge the effectiveness of temperature as a crystallization variable. Rather, use the difference in the solubility at different temperatures to gauge the effect temperature has on sample solubility. If an effect is observed, explore temperature as a crystallization variable.

- Temperature can affect different crystal forms and growth mechanisms.[12]

- When incubating experiments below and above room temperature and viewing experiments at room temperature, condensation can be a problem. To minimize and avoid condensation with vapor diffusion experiments, stack a dummy plate (with the reservoir filled with water and sealed) at the bottom and top of the stack of plates. This will slow the temperature change in the sandwiched plates and minimize condensation.

- The microbatch method works well for temperature exploration. In a traditional microbatch experiment, the relative supersaturation of the system does not change since in theory, there is no vapor diffusion. However, if the sample exhibits temperature dependent solubility, temperature can be used to manipulate sample solubility in a microbatch experiment. Another plus of using microbatch is the lack of condensation while viewing the experiment. Covers of microbatch plates can be removed for a clear view.

- Condensation with a hanging drop can lead to an alteration when the condensation mixes with the drop. In a sitting drop, condensation does not mix with the drop unless the condensation falls from above.

- To dry up condensation, add a small amount of concentrated salt solution to the reservoir. Keep in mind this might also further dehydrate your drop.

- Ideally, one should set the experiment at the eventual incubation temperature and all reagents, samples, and plates should be equilibrated to the incubation temperature. This is a reality for room temperature and 4°C setups for those of us with cold rooms. For the rest of us, we can set the experiment at room temp and then toss it into the incubator. Or, for 4°C setups, one can cheat. Simply incubate the reagents, sample, plates and slides in the refrigerator before set up. During the set up, place materials in a tray full of ice. Maintain the plates on ice during the set up. Seal and move smartly to the 4°C incubator.

- Nucleic acid temperature stability allows one to examine temperatures between 4 and 35°C.

- Increasing temperature increases the disorder of reagent molecules. Varying the temperature of a crystallization experiment can manipulate sample-sample as well as sample-reagent and reagent-reagent interactions. Such manipulations may have an impact on interactions which control nucleation and crystal growth. In addition, such interactions may have an impact on crystal packing as well as the termination of crystal growth.

- Temperature can be a habit modifier and change the crystal lattice. For example, at temperatures below 25°C and in the presence of sodium chloride and acidic pH, the tetragonal form of lysozyme is favored. Under similar reagent conditions above 25°C, the orthorhombic form is favored.[13]

- The preparation of heavy atom isomorphous derivatives can depend upon the temperature of the experiment. In most cases, it seems the soak temperature is the same as the crystallization temperature.

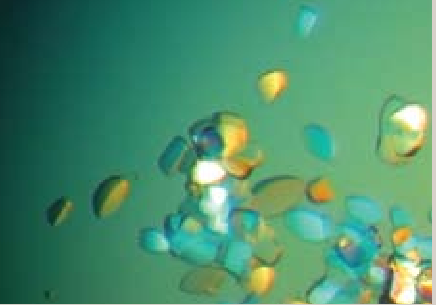
HAMPTON RESEARCH

TIPS FROM RAMC

Crystals of the Deinococcus radiodurans 50S ribosome subunit.

From the group of Paola Fucini, Max Planck Institute for Molecular Genetics, Berlin, Germany.



Filtering the Protein

Naomi Chayen

To reduce the number of crystals and increase their size, try filtering the protein solution prior to setting up the experiment. Try the following filter sizes: 0.22, 0.1 micron and 300 kD molecular weight cut-off. Try the Millipore centrifugal filters.

Pseudo-Microseeding

Mike Sintchak

When working with crystals that grow fairly rapidly (one day) try the following. Pipette multiple protein drops (2 to 4 works best) onto the cover slide. Using a single pipette tip, get the reservoir solution to mix with the first drop. Now, go back into the reservoir with the same tip to get the reservoir solution for the second drop. Continue for the remaining drops with the same tip. In certain cases, seeding starts very quickly, so by using the same tip one can introduce minute seeds to successive drops. Use the same cover slide with multiple drops to minimize evaporation.

Low Molecular Weight PEGs

Lesley Haire

When screening with low molecular weight PEGs try microbatch. Crystals appear rapidly with PEG 400-2000. To convert to vapor diffusion use 0.2 M buffer in the well and a 1:1 drop ratio. Try using a positive displacement pipette such as the Anachem Microman 1 - 10 µl. These are much more accurate.

Purest is Not the Best

Michal Harel

A protein which was purified and showed some faint bands of contaminants on a native gel was crystallized and solved successfully. The same protein, purified by HPLC and resulting in a single band native gel did not crystallize.

Cryoprotectant

Elspeth Garman

When making up cryoprotectant solutions containing glycerol, put a test tube of glycerol in a beaker of warm water. The viscosity falls and it is easier to pipette accurately.

Mass spectrometry

David Leys

We found mass spectrometry like ESMS and MALDI highly efficient in determining impurities and/or microheterogeneities in our protein sample/batch. In most cases it is a simple, straight forward method which requires a minimum amount of sample. In some cases it has shown to detect impurities/microheterogeneities when other techniques did not.

Shape of Drop

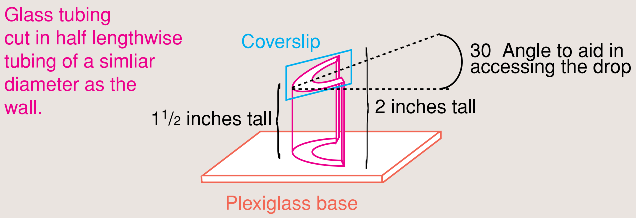
Ursula Kamlott, Hoffmann-La Roche: ursula.kammlott@roche.com

One of my proteins produced only zillions of tiny useless crystals when I mixed the drops the conventional way-mixing well, overlaying, etc. the protein with precipitant solution. Large, gorgeous crystals were produced when I crossed the drop, creating a gradient within the drop. This worked best, setting up sitting drops with vapor diffusion.

Don't Flip

Dennise Dombroski

When removing crystals from a hanging drop, I sometimes find that the biggest crystals fall against the coverslip and are impossible to resuspend without damage. I had our glass shop make a stand to transfer the coverslip that enabled me to manipulate the crystals more easily.



Glass tubing cut in half lengthwise tubing of a simliar diameter as the wall.
Coverslip
30 Angle to aid in accessing the drop
1 1/2 inches tall
2 inches tall
Plexiglass base

Extreme Soak

Jirundon Yuvaniyama

For soaking crystals with compounds with limited solubility I have tried two "extreme ways" (although not much- and more experiments should be tried):

- Leave some solid compound in the soaking solution.
- Dissolve some compound in n-octanol and layer the octanol solution on top of the soaking experiment.

These two provide (hopefully) more or less constant concentration of the compound in the soaking solution. The octanol layer may help reduce air oxidation by preventing direct contact of soaking solution to air.

I found that 200 µl of soaking solution in a well of the 24 well Linbro® plate is a good volume to work with:

—Not too little that possibly causes concentration change due to evaporation (Sealed well) and not too much that the crystals get lost in the solution.

The Glycerol Effect

Anil Mistry

Glycerol has many benefits but also some drawbacks. We found it to be beneficial with one protein we were working with; this protein is a transpeptidase called Mur A. The protein is quite soluble and could concentrate to 20 mg/ml but it lost activity over time when stored at 80°C. We therefore dialysed it into 50% v/v Glycerol to see if the activity could be retained for longer, this would allow us to make a large batch rather than regular smaller batches, for crystallisation. On dialysis we found a significant reduction in the volume of protein, so much so that the protein had concentrated from 5-10 mg/ml to almost 50 mg/ml. Activity was also found to be retained with no significant loss after 6 months at 80°C. This gave us a method for storing large batches of Mur A at 80°C, without losing activity and also resulted in a sample pre-concentrated for crystallisation and containing a cryo-protectant. Other sugars gave similar effects; sucrose, sorbitol, etc., but none were as effective as glycerol in achieving the 50 mg/ml final concentration.

Iodoacetic Acid
Bernie Santarsiero

Add a small amount of (~ 1%) iodoacetic acid to buffer solutions. This helps prevent aggregation by carboxymethylation of cys. Also, iodoacetic acid seems to help form salt bridges and aid in crystallization.

Soaking Crystals to Improve Resolution
Irene Weber

Try soaking poorly diffracting crystals in higher concentration of precipitate, ammonium sulfate, or PEG. It may take several weeks so test after 1 or 2 months.

Rapid Preliminary Screening of Protein for Aggregation Using Protein Quantities
Tom Zarembinski

When only small amounts of protein are available, it is not feasible to screen many compounds which promote monodispersim using a dynamic light scattering machine. To detect aggregation, we use a pseudo-native gel approach: 1 l of protein is mixed with 1 l of additive from Hampton Additive or Detergent Screens. These samples are then incubated at room temperature for 20-30 minutes and then placed in 2x sample buffer containing no DTT, no SDS and are not boiled. These samples are run on a standard SDS-PAGE gel. We have screened many additives using this approach and it has given us leads for subsequent optimization of protein buffers.

HPLC Profile
Glenn Dale

Keep an HPLC (Reverse phase) profile of your protein before crystallisation and after crystal formation. It can be used as a quality control and tells you if any modifications have occurred.

Don’t Throw Away Without Looking Close
Kalevi Visuri

Look closely at your old test tubes when cleaning the place. Proteins do crystallize on the walls of the tube when stored in a cold room. I picked up my tubes from the wastebasket and an x-ray was made from an old supersaturated protein tube.

Concentration of Protein without Aggregation
Paul Reichert

Use centipreps (millipore) for concentrating protein >O.5 ml. Protein concentrating away from membrane. (No micro high concentration, ppt on membrane), works very nicely for a number of proteins.

Preserve Hampton Solutions
Cheryl Janson

To preserve Hampton solution when you or a co-worker gets a “hit” and suspect the Hampton solution may be “magic” or you cannot reproduce crystals with lab-made solution, make the reservoir solution from lab ingredients and use your homemade solution for reservoirs. Use the Hampton “magic” solution only for the drops thus using a few µl per experiment rather than O.5 ml. Saves having a 48 well screening solution set with one tube empty and the rest at 8 ml and still allows the superstitions or in Alex’s case, the contaminated solution to reproduce crystals.

Recycle Your Precipitate
Neali Armstrong

If your protein refolding reaction has a low yield and produces lots of precipitate try collecting the precipitate, resolubilize in GuHCl, and refold again. This material is sometimes more pure than the washed inclusion bodies.

90% Solutions
Anna Stevens

When optimizing or making solutions for a random scan, omit the buffer (@ final O.1 M) so that your stock is 90%. Prior to putting your stock in the well, add 100 µl of 1M buffer of your choice. Next, add 900 µl of 90% stock and mix. This reduces the number of tubes for crystallization (precipitant) stocks and allows flexibility in buffer identity and pH range. Be sure to make plenty of (~20 mL) of precipitant, you’ll need 900 µl per buffer.

Check Both Liquid Nitrogen + Stream Flash Cooling
Hans Parge

If your crystal does not freeze well in the cold stream try liquid nitrogen or vice versa.

To Determine the Optimal Concentration of Your Protein for Screen I and Screen II
Jaru Jancarik

Try (setup) drop no. 6 first (of Screen I). It should produce light precipitation if ppt appears too heavy, reduce the protein concentration by 1/2 and try again. If there is no precipitation in drop 6 try drop 4. If there is no precipitation in either of the drops concentrate the protein 2 fold and try again.

Cryoprotectant Additive
Laura Pelletier

I tried adding 1-10 mg/ml BSA in the cryoprotectant when soaking crystals that would crack. The one time it was used, the crystal did not crack and froze nicely. I don’t know if the BSA was the reason for successful freezing. I was wondering if anyone else has tried this.

Slow Cryosoaks for Improved Crystal Stability
Bryan Prince & Melissa Harris

In a sitting drop well, cryoprotectant (20% Glycerol in crystallization buffer) should be dribbled down the side of the well.

Crosslinking of Crystals
Clare Stevenson

When crystals are fragile or you want to transfer them to a different mother liquor e.g. for heavy atom soaking, why not try crosslinking your crystals with

0.1% glutaraldehyde in your mother liquor. This can be done by adding the glutaraldehyde directly to the drop or placing it next to the drop and allowing for vapour diffusion. This crosslinking enabled us to solve Mod A at 1.2 A resolution.

Know When Enough is Enough!

Brent Segelke

As a graduate student, I spent countless hours and quantities of protein trying to get crystals of a single construct. We never got crystals. Another group got the structure of a homologous protein that was auto-digestive. Had we stopped after 400 trials and altered our construct, perhaps we would have faired better, we couldn't have faired any worse. There is a reasonable statistical argument to demonstrate that 400 trials are a good limit.

Buffer Screening

Anil Mistry

To find the best buffer system which will keep your protein happy, stable, and soluble for concentration prior to crystallisation, setup your protein (at 1-2 mg/ml) in hanging drops over 1 ml well solutions containing a series of buffers at various pHs, with various additives/stabilizers, etc. (but no precipitant!). Checking for drops which are clear will give an idea of which solutions keep the protein happy. In addition, as the system attains equilibrium some in situ concentration of protein will be induced due to the bulk difference between the drop and well volumes, hence an idea of how the protein behaves upon concentration in this solution will also be observed. Modifying a clear or slightly clear drop by adding a higher concentration of buffer to the well may even produce crystals. However, the main piece of information this method can produce is an idea of which buffer system and additives to put your protein into prior to concentration a crystallisation screening.

Soft Crystals

Allan D'Arcy

If you have crystals that are very sensitive to being touched (they break) or stick to the glass or dish, use a pointed strip of parafilm to move them. Otherwise, grow the crystals on parafilm and punch "wells" around the crystals to move it.

Crystal Annealing

Clare Stevenson

As I said in my talk, give it a go. You might be surprised!!

"No More 4°C"

Marie Anderson

Prepare trays for crystallisation, leave at 4°C, and fill polystyrene box or flat container with ice. Imbed a metal plate in the ice and set out cover slips. When you're ready to set out crystallisations place the trays in the bed of the ice and prepare drops, when finished transfer to 4°C. Simple but it works.

Cross Seeding to Generate Crystals of a Related Protein or Protein/Inhibitor Complex

Margaret O'Gara

If your protein or protein complex fails to crystallize try seeding from crystals of the same protein (if it's a protein you want to crystallize) or a related protein for apo protein crystals. Serial micro seeding works best, make sure you look at the drops after seeding to identify any visible crystal seeds in there (i.e. not new crystals).

Advice for the Follically - Challenged Crystallographer

Jonathon Hadden

It has been long accepted that crystallizers with an abundance of facial hair have highly successful careers (Leeds University personal observation). This was thought to stem from the fact that matter found its way from the hair into the trials and acted as a nucleation centre-BUT SERIOUSLY; Addition of small grains of sand to a crystallization drop that is "close to producing" crystals can aid in nucleation and crystal growth.

Raise the DMSO?

Melissa Harris

If higher DMSO does not damage your protein, try higher concentrations of DMSO (10-20%) for crystallization. It can help when dealing with insoluble compounds and is an excellent cryoprotectant. Freeze directly from drop!

TCEP as a Reducing Agent

Barbara Brandhuber

Use TCEP instead of DTT as a reducing agent in your protein solution. It isn't oxidized as quickly as DTT. Be sure to watch the pH of your solutions because it is very acidic.

Temperature Variation

Irene Weber

To grow crystals at different temperatures around room temperature search the lab for spots that are consistently at higher or lower temperatures. A difference of several degrees can be found. Temperature shifts can be easily made by moving crystals to a different place. (Check office shelves too!) [Discovered by Charles Reed in my lab]

Drop Drying Technique

Anil Mistry & Ron Rubin

When setting up drops with a protein which has low solubility a low starting concentration has to be used. Setup larger drops (5-10 µl) and leave them to stand "dry" for 3-5 minutes at room temperature /4°C prior to inverting over a well of a Linbro® plate, this should allow some pre-concentration.

TIPS FROM RAMC

Using DLS to Test for Irreversible Aggregation

Anil Mistry

Generally, people concentrate a protein to 10 mg/ml or higher, then dilute 2-fold when setting up their hanging drops by doing a 1:1 minx. What if in concentrating to 10 mg/ml aggregation has been induced which is irreversible, such when pipetting your 1:1 mix hanging drop, it already contains aggregates, a bad starting point.

(For monodisperse protein samples)

Using DLS test the limit of concentrated protein, i.e., the maximum concentration that can be achieved before a polydisperse signal is obtained. Then test samples, up to this limit, by concentrating up to this limit and test for irreversible aggregation by diluting a concentrated sample to a number of levels and test for monodispersity. With the sensitivity of current DLS equipment even samples at 10 mg/ml should be measurable. In this way and within the limits of your DLS machine it should be possible to find out whether you will have aggregates when you dilute your concentrated protein 2-fold when setting up a hanging drop.

Pickled Crystals Unusual Additives! (A True Story)

Michael Hickey

Pickle juice was added as an additive to a mutant form of a crystallized native protein. The mutant could not be crystallized in near similar conditions of the native. By chance, the components of pickle juice were read and found to contain compounds used in crystallization (i.e. glycerol, PEG 400, citric acid, acetic acid, alum, and a few vitamins). This juice (Sweet & Snappy Vlassic brand) was filtered (0.45 µl and adjusted to neutrality. It was then added to various PEG's (that crystallized the native form) and set up with the mutant. Crystals formed after 1 week! Trying to "add back" single components of the pickle juice to determine which component was responsible gave no crystals, the pickle juice (~1%) was necessary. Hint/ Tip: Commercially available food/ detergent solutions ought not be discounted as additives for crystallization!

Improve Your Crystals in Size, Shape, and Quantity

Nham Nguyen

After you have crystals, open the coverslip, remove the mother liquid in the droplet, dissolve the crystal with 3 µl of H20 or buffer and add 3 µl of well solution. Close the coverslip. The crystal will appear again. My crystals diffract ~ 4 A, sometimes I get twins that diffract ~2.5 A.

No Hits! What Next?

Anil Mistry, Pfizer

No hits from a screen, what next? You can always set up another screen! Or, you can make a list of all drops that have precipitate and use the precipitate as a potential seed stock. Streak seed from the precipitate into new drops that have been set up at 50% and 75% of the original screening solution. There may be nucleation sites or microscopic seeds in the precipitates that may grow at lower precipitate saturation. Better still, streak seed from the precipitate to a clear zone into the same drop to recycle the drop.

Micro-Seeding With A Cryoloop

Anna Aagaard, AstraZeneca

For reproducible micro-seeding by hand use a cryoloop to fish out your seed from the seed stock and transfer them to the drop. Use a 0.3-0.4 mm cryoloop.

Reduce To Enlarge

Zhanna Druzina, SGX Pharma

For bigger crystals try to add 0.5-1 microliter of 14 M beta-mercaptoethanol to the reservoir after the protein drop was set up.

Complex Screening

Annie Hassell, GlaxoSmithKline

Problem: Can grow crystal but no protein-ligand crystals. Tip: Take the conditions from the apo crystals and develop a focused optimization screen (24 well maximum). Screen complexes using cross seeding and the focused screen and three drop ratios (1:1, 2:1 and 2:3).

Change the Method

Annie Hassell, GlaxoSmithKline

Problem: Poor crystal quality. Tip: Change tray type or crystallization method. For example, initial screens done in sitting drop tray and crystal quality improved in 96 well hanging drop tray.

Watch Out For Ruts

Brandon Collins, Boehringer-Ingelheim

Every project, every protein, every construct is unique. Be careful of knowing too much. Just because things did or did not work in the past does not mean things will work that way for the next project.

Heavy Atoms To The Rescue

Problem: Poor diffraction. Tip: Heavy atom soaks to stabilize floppy regions of the protein.

Don't But All Your Eggs In One Basket

Joseph Luft, Hauptman-Woodward Institute

Don't focus all of your optimization efforts on a single crystallization condition. If you have several different crystallization conditions identified for a sample go after them. Crystals of the same protein produced from different chemical conditions and/or temperatures will have unique physical properties. These properties will determine how easy the crystal can be looped (physical stability), cryoprotected and ultimately how well the crystal diffracts X-rays. Avoid single points of failure, go after several hits.

This guide or parts thereof may not be reproduced in any form without the written permission of the publishers.

Insoluble Ligands

Doug Marcotte, Biogen IDEC

If ligands can't be soaked into crystal or co-crystallization is ligand specific try seeding into drops that contain ligand of interest. When soaking crystals with insoluble ligands try adding the cryoprotectant to the soaking solution. This can help solubilize the ligand and also cryoprotect (so less handling). Doesn't work so well when salt is the cryoprotectant, but may well when it's glycerol, DMSO or ethylene glycol.

Getting Away From Clear Drops

Annie Hassell, GlaxoSmithKline

Problem: Drops are all/mostly clear. Tip: Remove stabilizing agents (salt, glycerol, etc) from the protein buffer. Then do crystallization screens.

Avoiding Excessive Precipitation

Vaheh Oganesyan, MedImmune

At suboptimal protein concentrations the interface between protein solution and crystallization screen solution may exhibit excessive precipitation. To avoid this, before adding screen, solution add 1 microliter of water. Downside of this is equilibration will take slightly longer. Upside of this is decreased osmotic shock for protein and less precipitation.

Heavy Precipitate Control

Janet Newman, CSIRO

Put one conditions of 40% TCA into your standard screen. This should precipitate out all of your protein, so that you have an idea of what heavy precipitate should look like.

Look At The Big Picture

Edward Snell, Hauptman-Woodward Medical Research Institute

Don't consider a crystallization result in isolation. Look for neighbors in chemical space and use those results to provide chemical directions for optimization. If a cryocooled crystal does not diffract well. You cannot tell if it is the crystal, cryoprotectant or cooling that is causing the problem. Look at room temperature data before moving on.

Poor Nulceation

Mei Xu, Novartis

Consider the case of poor nucleation and seeding did not work. Tip: Mix protein and well solution then use pipette tip to cross the drop into branched shape. Crystal may grow in the branches of the drop.

Seeding Suggestion

Paris Ward, GlaxoSmithKline

To increase you choices of producing more optimal crystal condition or conditions using seeds, try the following. Program a small volume liquid handler to dispense your protein and seed solution directly into 96 well commercial screens and/or an additive screen.

Delete To Succeed

Heidi Schubert, University of Utah

Recent success with loop deletions. Sequence alignments reveal either charged loops and/or loop insertions relative to homologues. I have removed 3 to 34 amino acids and retained high expression soluble protein and novel crystals.

Seeking Stability

Annie Hassell, GlaxoSmithKline

Problem: Unstable protein. Tip: Add 1-5% low molecular weight (200 to 1,000) PEG directly to the protein and then screen.

Doh!

Jim Pflugrath, Rigaku

Start with big crystals! Add at least 5% glycerol to everything.

Stabilize For Cryo

Laura Pelletier, SGX Pharmaceuticals

Stabilize crystals in cryo by adding protein buffer components into the cryo. For example, most commonly I add 100 to 150 mM NaCl plus reservoir components plus cryoprotectant(s).

Ratios

Ayse Sinem Ozyurt, SGX Pharmaceuticals

Play with protein-mother liquor ratio, especially with low solubility proteins. Try different concentration of protein coupled with streak seeding.

Eliminate One Offs

Nancy Bump, Millennium Pharmaceuticals

After looking at the results of initial screening or of additive screen, pick several of the best "hits" and screen in 96 well format, 6 or 8 identical drops of each favorite before scaling up. Helps to eliminate "one offs" and save time.

Complex It!

Paul Reichert, Schering Plough Research Institute

Apo protein is monidisperse but won't crystallize. Complex it! Complex it! Complex it!

Matrix Seeding Tweak

Armando Villasenor, Roche Palo Alto

If your crystal seeds withstand large serial dilutions, try matrix seeding via the reservoir by doing the following. 1) Create crystal seeds as described by Allan D'Arcy. 2) Dispense seed into reservoirs containing reservoir. 3) Aispirate/dispense to mix seed in reservoir. 4) Dispense mother liquor droplet containing seed onto protein drop.

A Little Salt Please

Neil Grodsky, Pfizer Global Research & Development, La Jolla Labs

If you do not see any crystal growth in several days after set-up (more than 1 to 2 weeks) and the drop are not all clear, add salt (such as ammonium sulfate) to 0.5 M to the drops. Even though ammonium sulfate salt crystals might form, you might actually get protein crystals. This worked for me recently.

Urea To Solubilize

Gloria Borgstahl, Eppley Institute UNMC

Non denaturing (less than 3 M) concentrations of urea can be helpful to solubilize your protein.

Multivalents

Simon Low, Pfizer, Inc.

Try stoichiometric levels of multivalents, cations as additives. They may be necessary for crystallization but sometimes the levels found in commercial screens are too high and toxic.

Cooking for Crystals

Liping Wang, GlaxoSmithKline

Heat treatment of protein complex to obtain diffraction quality crystals. Original complex has no initial crystal hits. Heat treat protein complex (25 to 80 degrees Celsius) for various times (5 to 30 minutes). Centrifuge to get rid of aggregated protein and screen again.

Toothpick Tip

Paul Reinfelds, Illinois Institute of Technology

When using pre greased trays, take a toothpick and remove a bit of grease from each well. Now as you push down on your cover slip, you turn it a few degrees. This will allow the air to escape and the turn will form an airtight seal over each well.

Thermofluor To The Rescue

Jackie Day, Pfizer St Louis

Thermostability. Monitor the effect of additives, buffers, ligands, etc. on melt temp of your protein. We have seen in multiple cases that the most thermostable construct, buffers, additive yields the best or only crystals. How? We use Bio-Rad's iQ5 iCycler (a PCR instrument) as it has 5 sets of filters for excitational emission and hydrophobic dyes that fluoresce upon binding (protein unfolding).

Getting Out Of A Sticky Situation

Michael Wiener, University of Virgina

Problem: Crystals adhering to plastic of sitting drop plate, and mechanical dislodging (by cryoloop, tool, etc) does not work. Solution: Stan a fine gauge syringe needle into the plastic, near but not into the crystal. This often distorts/disrupts the plastic near the crystal and breaks the seal.

Liquid Bridge

Margarete Neu, GSK Stevenage, UK

Getting bigger crystal by low tech / low cost counter diffusion. If you are faced with either no nucleation or showers of crystals and the usual tricks including seeding do not work, try this: On a cover slide, set the protein and precipitant drop (example 1 microliter plus 1 microliter) separate, but very close to each other. Then, with a whisker or pipette tip streak through the drops to form a connecting bridge between the protein and precipitant solution. Invert cover slide and place over well. Crystals will form along the gradient and "self screen" for best conditions.

Low Concentration Complexing

Elizabeth Fry, Abbott Laboratories

When working with compounds for co-crystallization, if the compounds are highly insoluble in protein buffer (50 micromolar or less) we often employ low concentration complexing. We dilute the protein and then add in diluted compound, so tha the compound is added close, or at least closer to a concentration where it is soluble and the content of DMSO in the protein sample remains less than 2%. The protein-compound complex is then concentrated for crystallization trials. This has helped us with several projects with highly insoluble compounds.

Ionic Liquids

Christopher Bonagura, Exelixis, Inc.

In experiments using model proteins we found that Ionic Liquids (IL's) specifically 1-Butyl-2-methyl imidazolium chloride gave increased numbers of crystallization outcomes compared to the IL controls. A large number of the crystals obtained had precipitated outcomes in the IL controls. In many other cases the IL and crystal had an improved morphology (needles to plates, plates to 3D crystals) over the IL controls. Tip: Using an IL such as 1-Butyl-2-methyl imidazolium chloride as an additive to improve chances of getting a crystal from conditions which otherwise would give precipitate. Marc Pusey, MI Research, Inc. Our favorite cryoprotectant. 1x UCP (Ultimate Cryo Protectant) 8% Glycerol, 8% Ethylene glycol, 9% Sucrose, 2% Glucose. We make a 2x solution. Generally add this 1:1 with reservoir. The ratio can be modified, for example 1.2 microliter 2x UCP : 0.8 microliter reservoir, or 1.4 microliter 2x UCP : 0.6 microliter reservoir, or 0.6 microliter 2x UCP : 1.4 microliter reservoir, etc. I believe this has been successful in cryoprotecting some 70% of all of our systems, resulting in more than 50 solutions of these targets regardless of previous cryogenic treatments. Author in unknown to me, but the credit is published in a singled Hencrickson paper. I was tipped off 6 years ago.

Protect The Bridge

Shirley Robert, York Structural Biology Laboratory

If you can't get your Se-met protein to crystallize try leaving out the DTT/TCEP during purification and crystallization. Sometimes there are disulfide bridges near crystallization contacts that need preserving for crystallization to take place. Collected the Se edge is still possible.

DMSO For Cryo

Rich Romero, SGX Pharmaceuticals

Try 20 to 30% DMSO as cryo. This has worked well in a number of cases for me and I've added this to a very short list of cryos that I personally use. Note: If your mother solution contains a high salt concentration the DMSO will cause it to precipitate out of solution. So beware!

No Fog

Beat Blattmann, University of Zurich

4 degrees Celsius crystallization plates prepared at room temperature always have a condensation problem on the plate seal. To avoid condensation cover the finished plates with two lids and plate it in the cold room for 20 minutes or on top of a cold metal block, The will reduce the temperature of the reservoir solution while the 2 lids delay the temperature change from the top long enough to avoid condensation.

Anti Slip Tip

Barbra Pagarigan, Celgene

Ever been manually sealing a plate only have it slip out from under you? The result is usually death for hanging drop plates, and with sitting drop plates your best bet is hoping the drop is not splashed onto the seal above. To ensure the plate stays put when applying pressure, we use a "grip pad" in our lab. Simply place the grip pad onto the bench, set plate on top and seal as usual. The grip pad prevents the plate from slipping out from under the compression tool, usually a brayer, used for ensuring the please seal is applied correctly. The grip pad can be cut from the material commercially available for lining tool shop drawers. In addition, we created a fixed plate holder that encloses the entire plate to guarantee the brayer does not slip off the plate when sealing, a common occurrence when manually sealing many plates. Our plate holder is custom cut from a hard rubber to fit both thee 24 well and 96 well plates. The plates sit slightly above the platform to ensure both ends are sealed and for easy removal. The sides of the platform are rounded to ensure the brayer has a smooth path of travel.

HAMPTON
RESEARCH

CRYSTALLIZATION TIPS FROM A TO Z

Crystals of apotransferrin (bovine milk) grown in fumaric acid, pimelic acid, sebacic acid, hexadecanedioic acid, maleic acid, glutaric acid, suberic acid, dodecanedioic acid, oxamic acid, 15% w/v polyethylene glycol 3,350.

Peter Nguyen, Hampton Research, USA.

A is for Aggregation

Aggregation can be a deterrent to the crystallization of biological macromolecules including proteins, peptides, and nucleic acids. The presence of sample aggregation can be detected by either dynamic light scattering or native gel electrophoresis. Aggregation might be caused by hydrophobic patches on the surface of the sample, differently charged isoforms, differently phosphorylated isoforms, mixtures of methylated and non-methylated samples, glycosylation, as well as electrostatic interactions. Aggregation can be due to autologous aggregation where the protein is aggregating with itself or heterologous contamination where the sample is aggregating with other proteins. In the case of heterologous contamination, further purification of the sample should be seriously considered. In the case of autologous aggregation that precludes crystallization, one might consider:

Using molecular biology to manipulate intra and inter molecule interactions by modifying the sample sequence (alter, add, or delete residues).

Using chemical additives, like those listed below, to manipulate sample-sample and sample solvent interactions:

- Detergents
- Chaotropes (urea, guanidine hydrochloride, hydrochloric acid, etc.)
- Electrostatic agents
- Alcohols (isopropanol, methanol, ethanol, etc.)
- Salts (sodium chloride, potassium chloride, sodium fluoride, etc.)
- Polyols (glycerol, PEG 400, etc.)
- Ligands, inhibitors, co-factors, and metals
- Use temperature to prevent aggregation (0°C and 60°C)
- Consider a fusion protein
- Remove C-terminus or N-terminus
- Truncate domains
- Remove His-tag

In some cases aggregates can be removed by centrifugation or filtration.

In some cases the aggregates can be removed by mixing the sample with the crystallization reagent, allowing the sample to incubate for 15 minutes, centrifuging the sample/reagent mixture, removing the precipitate, and setting the drop with the supernatant.

B is for Birefringence

The technical mumbo jumbo first. The physical properties of isotropic materials, such as glasses, liquids, and amorphous materials, do not depend on direction. However, most properties of a wide variety of crystals (including liquid crystals) do show such variation. This anisotropy of physical properties originates in the anisotropic build-up of the materials (crystal structure). Anisotropy in the optical properties of uniaxial crystals is referred to as either birefringence or dichroism, depending on whether the index of refraction or the absorption coefficient is concerned. Birefringence means that there are two distinct speeds with which light can propagate, depending on the direction of propagation. When a light ray splits into two beams as it passes through a material, the effect is called birefringence (or double refraction) and the material is birefringent. If you look at something through a birefringent material, you'll see double. The word birefringence comes from the Latin bi- (twice) plus refringere (to break up). Thus, the light rays are "broken in two" by a birefringent material. One well-known example of a birefringent medium is crystalline calcite (calcium carbonate). If you look at the world through a clear crystal of calcite (calcium carbonate), you will see double. Place such a crystal on a drawing, and you'll see two overlapping copies of the drawing. The molecular structure of calcite causes double refraction, in which each light ray is split into two rays that emerge from the crystal at slightly different angles. Calcite shows this more clearly than most crystals, but quartz and many other crystalline minerals also split light ray.

Now, the practical interpretation for crystal growers. You might hear the word birefringence used quite often by crystal growers when viewing crystals under a microscope. Here, crystal growers are stretching the definition of the term birefringence to describe the colorful display produced by biological macromolecular crystals when polarized light is passed through the crystal.

A light microscope with polarizing optics is required to observe birefringence. The following path is a typical setup. Light passes from the light source through the first polarizing lens, then the specimen (crystal) then the second polarizing optic, the magnifying optics and then into your eye. On many typical polarization setups, the second polarizing filter can be rotated while the specimen is stationary. Rotating the polarizing optic without something to rotate the plane of polarized light in the path (i.e. a crystal) will result in one seeing light, dark, light, dark, as the filter is rotated. But if a crystal with birefringent properties (i.e. a biological macromolecular crystal) is positioned in between the two polarizing filters, one will observe changing colors as the polarizing filter is rotated. Specifically, when the polarizing filters are aligned such that the field is dark, a birefringent object (crystal) will glow with color.

Birefringence is one way we can differentiate amorphous precipitate from microcrystals in a drop when viewed under a microscope. Precipitate does not have birefringent properties while most biological macromolecular crystals do.

One drawback with using birefringence in today's crystal growth world is that most of the crystallization devices utilized are made from plastic such as polystyrene and polypropylene. These plastics are optically active and can be birefringent. In fact, often times the colors we see displayed in crystals are contributions from the plastic birefringence. However, it is still possible to observe microcrystalline birefringence in the plastic trays, but there is usually a contributory effect from the plates used to grow the crystals. One way to avoid this is to grow crystals in a glass device or at least observe the crystals in a path that is free of birefringent plastics.

Birefringent precipitates will glow, sparkle, or glisten.

To test for birefringence, position the polarizers so the field of view is dark WITHOUT they crystallization plate or setup. Place the tray into position on the microscope. If a crystal is birefringent, some of the light passing through the crystal will be rotated and pass through the second (analyzing) polarizing filter. The intensity of the transmitted light will increase and decrease as the crystal or the polarizer is rotated. Remember, birefringence is not ALWAYS clearly visible when plastic is in the light path (i.e. when you use plastic slides or crystallization plates). However, a birefringent crystal viewed in a plastic tray or plastic cover slide will have a different color than the background (i.e. plastic plate) or foreground (plastic slide). Finally, birefringence is a property of crystals, both biological (proteins, peptides, and nucleic acids) and inorganic crystals (salts). Birefringence is MORE pronounced in inorganic crystals (salt).

A quick comment on what to do with birefringent precipitates. Streak seeding is a common and often successful method of taking advantage of microcrystalline precipitate to grow large single crystals. But that starts with an S so we cannot talk about that this time!

C is for Condensation

Condensation on cover slides or tape may be a problem when incubating plates at cool or warm temperatures.

To minimize condensation try the following: Place a dummy plate above and below the plates being used for crystallization. For example, on a stack of 5 or 10 plates, place a dummy plate on the bottom of the stack as well as the top of the stack. The reservoirs (wells) of the dummy plates should contain water as the reservoir solution. The reservoirs should be sealed either with plain glass cover slides and vacuum grease or clear sealing tape to prevent the reservoir solution from evaporating.

Pipet the reservoirs and drops at the temperature where the plates will be incubated. This means enjoying a cold room during setups. One can cheat and avoid a cold room by incubating reagents, pipet tips, plates, and slides at the cold temperature. When ready to set the experiment, set the plates in an ice bath and quickly set the plate while the plate (as well as reagents and protein) are on ice. Conceivably one could also do this for warm temperature incubations where an elevated temperature incubator is available. The idea is to avoid a RAPID change in temperature with the sealed crystallization experiment (plate). By minimizing the temperature difference between the setup and incubation temperatures, condensation can be minimized.

Try sitting drop vapor diffusion. Condensation is especially bad for hanging drop vapor diffusion experiments since water condensing on the slide can run or merge into the crystallization drop. To avoid such a merger, try sitting drop vapor diffusion. Condensation on the tape or cover glass above a sitting drop experiment may still make viewing the drop difficult, but at least the drop will not become diluted with condensation unless the condensation is so bad that it rains in your experiment!

Finally, avoid vapor diffusion altogether and go microbatch.

D is for Drafts

Temperature is often a significant and overlooked crystallization variable. Temperature can sometimes be an unwanted crystallization variable in labs subject to temperature changes. Temperature fluctuations are especially troublesome because unless they are intentional and accurately produced and recorded, the temperature changes are difficult or impossible to reproduce. Keep the following in mind when selecting a location to store crystallization experiments:

How does the temperature of the room fluctuate over the course of a day, over the weekend, during the month, over the year?

Place a thermometer in a container full of water (allowed to equilibrate to the location temperature) and observe the temperature fluctuation over time to determine the temperature stability of the location.

Is the area subject to drafts such as opened and closed doors, under a heating or air conditioning duct, or near a heat producing device?

Avoid storing experiments near windows or walls that are in contact with the outside of the building.

Is the heating or air conditioning turned off in the evening or on weekends in your facility? If yes, substantial temperature changes can occur, especially during very cold or hot days/nights.

In an effort to maintain a more constant “room temperature”, store the plates in a quality, commercial incubator set at the desired “room temperature”. Since most of us cannot swallow spending money for a room temperature incubator, consider storing the plates in an unplugged or non-working refrigerator, styrofoam box, ice box, or cooler.

Use a quality incubator to store crystallization experiments.

E is for Ethylene Glycol

Ethylene glycol. Also known as 1,2-Ethanediol as well as glycol. Molecular mass of 62.07. HOCH$_2$CH$_2$OH. A nice little polyol that can be useful as a cryoprotectant. Typically used as a cryoprotectant in the concentration range of 10 to 30% v/v. Also useful as a non volatile organic additive when used in the concentration range of 1 to 5% v/v and in some cases, much higher (15 to 25% v/v). As an additive, ethylene glycol has been reported to sometimes increase the size and quality of the crystal. Finally, it is useful as a crystallization reagent in the concentration range of 25 to 30% v/v. It is even thought that ethylene glycol can have a structure-stabilizing effect and may be useful in the crystallization of flexible proteins.

F is for Fab Fragments

Fab and Fv fragments can be used as co-crystallization agents.

Fab fragments have decent solubility properties and bind specifically to antigens with reasonable equilibrium constants (105 to 108 M-1). Fab fragments can, in some instances, effectively transform aggregated protein into soluble, monodisperse protein, suitable for crystallization trials. Since antibodies are frequently available from related biochemical studies, they can often be applied more readily than molecular biology (point mutants, truncations, molecular engineering). However, it seems MOBO gets faster and easier with each passing year. It is often useful to consider screening several different Fab fragments that recognize different epitopes for crystallization trials. Sometimes Fab fragments can immobilize a region of a protein sample, reducing sample flexibility, enhancing conformational homogeneity of the sample which in turn can enhance chances for crystallization.

Using an Fv fragment in lieu of a Fab fragment might have some advantage since there is no flexible elbow to inhibit crystallization.

When preparing antigen-antibody complexes for crystallization, one should carefully select the antibody, prepare a homogeneous Fab species, and prepare the Fab-sample complex with proper stoichiometry. Ideally the Fab should not interfere with the native sample conformation or activity.

The presence of a Fab fragment in the crystal can assist in the crystallographic structure determination by allowing one to utilize molecular replacement.

Fab and Fv fragments should be considered useful tools in the crystallization toolbox for manipulating sample solubility, conformational flexibility, and crystal lattice contacts, as well as being a possible tool for molecular replacement.

Reference:

The use of antibody fragments for crystallization and structure determinations. LC Kovari, C. Momany and MG Rossman. Structure 15 December 1995, 3: 1291-1293.

G is for Gap

When greasing crystallization plates, it is often useful to leave a small gap in the bead of grease applied to the plate. For example, begin greasing at 12:00 and apply the bead clockwise until 10:00. A gap with no grease is left between 10:00 and 12:00. Place the cover slide onto the bead of grease. Depress the slide onto the grease. As the slide is pressed onto the bead of grease, pressure is allowed to escape through the gap. Before the slide bottoms out on the plate, twist the slide approximately 15 minutes (90°) to smear the grease across the gap and properly seal the cover slide to the plate.

H is for 1,6 Hexanediol

1,6 Hexanediol ($C_6H_{14}O_2$ M_r 118.18) is a non-volatile alcohol which most likely precipitates biological macromolecules by lowering the chemical activity of water. Non-volatile organics can be effective crystallization reagents for proteins and are particularly appropriate for nucleic acids. This non-volatile alcohol steals water molecules from the biological macromolecule through hydrogen bonding and reduces the electrostatic screening effectiveness of the water. Typical stock solutions of 6.0 M (about 71% w/v) are typical for this crystallization reagent. Typical reservoir concentrations for this reagent are 1 to 4 M across a broad pH range. 1,6 Hexanediol can be utilized in the presence of numerous anions and cations, as well as a broad range of salts. It can be a substitute crystallization reagent for MPD, PEG 400, and PEG MME 550. It can also be utilized as an additive in the concentration range of 0.1 to 0.2 M. 1,6 Hexanediol is a waxy solid or flake. When formulated with water, the reaction is endothermic and one might need to warm the solution to effect complete dissolution at high levels of supersaturation.

1,6 Hexanediol is utilized as a precipitant in Crystal Screen 2 and is available as a preformulated, sterile filtered reagent from Hampton Research (Catalog Number HR2-625; 6.0 M 1,6 Hexanediol, 200 ml).

I is for Interface Diffusion

Crystallization by interface diffusion was popularized by Ray Salemme (F.R. Salemme 1972, Arch. Biochem. Biophys. 151, 533). The method is also called free interface diffusion and liquid-liquid diffusion. The methodology is straightforward. Interface diffusion is classically performed in a cylinder with a small diameter, such as a capillary. Using a capillary with both ends open, the sample is pipetted into the capillary. Next, the crystallization reagent is added to the capillary. For true interface diffusion to occur, the sample and the reagent should touch one another inside the capillary. This can be accomplished by making sure the sample is positioned at the inside end of the capillary before adding the crystallization reagent. When adding the crystallization reagent, use a pipet tip with a small diameter opening such as a gel loading tip. Carefully and slowly pipet the reagent from the pipet tip and allow a bead of the reagent to form at the tip. Hold the capillary parallel to the ground and gently touch the tip of the capillary to the reagent bead. With a combination of gently pipetting, capillary action and proper capillary tilt, fill the capillary with the appropriate amount of crystallization reagent without air gaps. Done correctly, the inside of the capillary should contain a single cylinder of liquid. Filling the capillary should be done gently and slowly to minimize mixing the sample and the reagent. Actually, one should add the more dense solution into the capillary first, followed by the less dense solution to minimize mixing. If done properly, one can see an interface between the sample and the reagent. It might be best to start with equal amounts of sample and reagent. Later, one can vary the ratio of sample to reagent for optimization. Once filled with reagent and sample, the capillary can be sealed with a non-drying clay or wax (sealant). Be careful not to add too much sealant at a time to the end of the capillary since the sealant will displace the liquid in the capillary and too much sealant will result in liquid being lost from the capillary. Storage of the capillary can be done in several ways. Some like to simply stick the capillaries vertically into clay or wax. But this means one must remove and contort the capillary for viewing under a microscope. Instead, one can use a petri dish (square ones work really well) and line the petri dish with two thin lines of wax or clay about the size of a toothpick. The lines of wax or clay should be parallel to one another and positioned apart from one another just under the length of the capillary. The capillaries can be set upon the lines of clay in neat rows. A dozen or so capillaries can be stored in a small square petri dish. Storage and viewing is quick and simple. The petri dish also facilitates easy labeling.

A nice feature of interface diffusion crystallization is the potential of a concentration gradient of sample and reagent along the length of the capillary. Although pipetting, gravity, and movement make this interface and gradient less than perfect, gradients do form and one can often visualize the concentration gradient as crystals of different size and number form at different points along the gradient (length of capillary), presumably due to the change in relative supersaturation along the length of the capillary. For example, numerous, small crystals might form at high levels of supersaturation, fewer and larger crystals might form at ideal levels of supersaturation, and no crystals may form at very low levels of supersaturation.

Permutations of interface diffusion include the following. Doing it in microgravity. Freezing one layer before adding another to ease pipetting (good for larger volumes). Freezing the entire experiment then slowly melting the slug to introduce temperature as a crystallization variable. Placing a gel plug between the sample and the reagent. Using high throughput plates with tall, thin cylinder-like wells for “vertical” interface diffusion.

J is for Jeffamine® Reagent

The Jeffamine polyoxyalkyleneamines contain primary amino groups attached to the terminus of a polyether backbone. They are thus “polyether amines.” The polyether backbone is based either on propylene oxide (PO), ethylene oxide (EO), or mixed EO/PO. Jeffamines are synthesized as either monoamines (M-series), diamines (D series), or triamines, and are made in a variety of molecular weights, ranging up to 5,000. The ED-series are aliphatic diamines structurally derived from the propylene oxide capped polyethylene glycol.

The wide range of molecular weights, amine functionality, oxide type, and distribution provides flexibility in synthetic design of compounds made from Jeffamine Reagents. For the most part, Jeffamine Reagent products undergo typical amine reactions and are low viscosity liquids, exhibiting low vapor pressure.

Jeffamine® Reagents originated chemically at the Texaco Chemical Company as lubricants and fuel additives and are now most frequently used in manufacturing adhesives, coatings, epoxies, and curing agents. Scary what we crystal growers will use as crystallization reagents, is it not?

Jeffamine Reagents worked their way into the protein crystallization community in the late 70's when Dulio Cascio (then in the lab of Alexander McPherson at the University of California Riverside now University of California Los Angeles) evaluated them as polymeric precipitants "similar" to the polyethylene glycols.

Alexander McPherson published the use of Jeffamine Reagents in a crystallization publication "Two approaches to the rapid screening of crystallization conditions" J Crystal Growth 1992, 122: 161-167.

The first protein structure solved using Jeffamine Reagents was that of Xylose Isomerase in the publication by Lloyd et al, "Crystallization and preliminary X-ray diffraction studies of xylose isomerase from Thermoanaerobacterium thermo sulfurigenes strain 4B" J Mol Biol 1994, 240: 504-506.

Jeffamine Reagents are discussed by Lesley Lloyd Haire and others in Terese Bergfor's wonderful book "Protein Crystallization - Techniques, Strategies, and Tips, A Laboratory Manual (IUL Biotechnology Series 1999 ISBN 98-075232).

The following Jeffamine Reagents have been tried in protein crystallization experiments:

- Jeffamine D-230 Reagents
- Jeffamine D-400 Reagents
- Jeffamine ED-600 Reagents
- Jeffamine ED-900 Reagents
- Jeffamine ED-2001 Reagents
- Jeffamine M-600 Reagents

Hampton Research has experienced the most success with Jeffamine ED-2001 Reagent and Jeffamine M-600 Reagent.

Jeffamine Reagents can be used "like polyethylene glycols" in the crystallization of proteins, peptides, and nucleic acids. In fact, some crystal growers substitute Jeffamine Reagents for PEGs during optimization to see if using them can improve the crystals or offer new conditions for further optimization.

Jeffamine Reagents can be formulated with most of the salts, buffers, organic solvents, and additives used in biological macromolecular crystallization.

There is very little literature describing the use of Jeffamine Reagents as crystallization reagents and not a single report of them being used as a crystallization reagent in the Biological Macromolecular Crystallization Database at the time of this writing.

(http://wwwbmcd.nist.gov:8080/bmcd/bmcd.html)

Obtaining crystals in Jeffamine Reagents is a mixed bag. It is a good thing since there are crystals. It is a bad thing since they are a pain to formulate.

The formulation of Jeffamine Reagents as crystallization reagents is tricky and tedious. They are very alkaline chemicals and must be titrated to neutrality or the desired experimental pH before use. Titration is typically performed using hydrochloric acid. A significant amount of hydrochloric acid must be used to titrate the Jeffamine Reagents to pH values between 2 and 11. pH changes are slow until pH 9, and change very rapidly as one approaches neutrality. The addition of hydrochloric acid results in a significant temperature increase in the reagent. Accurate pH recordings require repeated pH, cool, pH, titrate; repeat cycles. Many salts, including anions and cations, can be used in conjunction with Jeffamine Reagents. Typical salt/Jeffamine Reagent ratios and concentrations are similar to those used with "related" polyethylene glycols. Phase separation can be a bigger problem with Jeffamine Reagent / salt mixtures than for PEGs, but can be minimized by titrating the Jeffamine Reagent to neutrality or close to the final working pH before adding the salt and/or buffer. Having as much water present in the formulation also helps prevent phase separation.

Jeffamine M-600 Reagent is utilized as a crystallization reagent in Crystal Screen 2 (Catalog Number HR2-112).

Hampton Research offers the following preformulated, ready-to-use Jeffamine Reagents:

Jeffamine ED-2001 Reagent 50% w/v solution pH 7.0, 200ml sterile filtered (HR2-597)

Jeffamine M-600 Reagent 50% w/v solution pH 7.0, 200ml sterile filtered (HR2-501)

Hampton Research also offers the following Jeffamine Reagent which has not been titrated:

Jeffamine M-600 Reagent 100% solution pH >12, 200 ml (HR2-503)

Jeffamine is a registered trademark of the Huntsman Petrochemical Corporation.

K is for Krypton

Named from the Greek kryptos or "hidden", krypton is neither green, nor a solid material that can defeat Superman. Rather it is another noble gas discovered in 1898 by Ramsay and Travers. It ranks sixth in abundance in the atmosphere. Krypton gas is used in various kinds of lights, from small, bright, flashlight bulbs to special strobe lights for airport runways. As with the other noble gases, krypton is isolated from the air by liquefaction.

Krypton and crystals. The use of xenon and krypton at high pressure is becoming a popular method for the phasing of proteins. There are several homemade as well as commercially available pressure cells for creating xenon and krypton derivatives.

In essence, the crystal is exposed to the krypton or xenon gas at high pressures for a short period of time in order to allow the krypton or xenon to bind to the protein within the crystal. Following incubation and depressurization, the crystal is flash cooled in liquid nitrogen and mounted onto a goniometer in a cryostream for X-ray diffraction analysis. Freezing of the crystal is necessary to prevent the diffusion, release and loss of gaseous krypton or xenon. As a side note, methods of generating and analyzing xenon derivatives in glass or quartz capillaries have been described (see references below).

Krypton and xenon binding sites are generally different from those for other heavy atom sites so the screening of krypton and xenon can be used as a follow up when the initial soaks in heavy atoms are not successful.

When the specialized hardware is available for screening krypton and xenon under high pressure, the method is a convenient and rapid way for screening successful derivatives for phasing.

L is for Lyophilization

Avoid lyophilization of your protein for storage and concentration if you plan to use it for crystallization experiments. Lyophilization is a not-so-gentle procedure and can prevent crystallization. Yes, we know that lyophilized lysozyme will crystallize quite readily as well as other "Sigma proteins" but we have seen, as well as others, many a protein that will not crystallize following lyophilization. And we have yet to see a protein that would only crystallize after lyophilization. So don't go there.

If you have a lyophilized protein, there is hope. First of all, one should solubilize the protein in water or a stabilization buffer and dialyze the protein exhaustively against water or the stabilization buffer. Dialysis is an important step which will help to remove residual, non-volatile buffers and reagents, as well as low molecular contaminants.

L is for Lipidic Cubic Phases

Membrane proteins can be crystallized in a lipid phase where the crystallization detergent diffuses into the lipid phase and crystal growth proceeds through lateral diffusion of the protein molecules.

L is for Light Scattering

Dynamic light scattering, also known as DLS, also known as photon correlation spectroscopy, also known as quasi-elastic light scattering, can be utilized to screen crystallization candidates for monodispersity.

DLS measures the translational diffusion coefficient of a macromolecular undergoing Brownian motion in a solution. What? In essence, DLS measures the intensity of light scattered by molecules in solution. In turn, this measurement can tell you the size distribution of the protein molecules in solution.

Crystal growers should use DLS to differentiate monodisperse solutions from polydisperse solutions. Homogeneous, non-aggregated monodisperse proteins have a high probability of producing crystals. Proteins with non-specific aggregates and heterogeneous samples are less likely to crystallize. DLS allows one to screen protein samples quickly, with small volumes of sample, at different temperatures. The procedure is non-invasive so the protein can be recovered. If DLS is not an option, one can obtain similar results using native polyacrylamide gel electrophoresis or size exclusion chromatography. But DLS is faster and more sensitive.

For a great story on DLS, as well as practical information on methods for DLS, read Terese Bergor's chapter on Dynamic Light Scattering in Protein Crystallization - Techniques, Strategies, and Tips - A Laboratory Manual.

M is for Mass Spectrometry

Mass spectrometers (MS) use the difference in mass-to-charge ratio (m/e) of ionized atoms or molecules to separate them from each other. MS is therefore useful for quantitation of atoms or molecules and also for determining chemical and structural information about molecules. Molecules have distinctive fragmentation patterns that provide structural information to identify structural components.

MS can be a nice tool along with Dynamic Light Scattering (DLS), sodium dodceyl sulfate polyacrylamide gel electrophoresis (SDS PAGE), iso-electric focusing (IEF), and size exclusion chromatography (SEC) to evaluate the purity, homogeneity, and monodispersity of the sample prior to crystallization. Likewise, if crystallization problems exist, MS can be a nice tool to identify possible sources of the problem. MS can also be used to detect and possibly identify impurities in crystallization reagents.

In the case of recombinant protein samples, an accurate measurement of the molecular weight will inform one about the presence of post-translational modifications. Dependent on the physical properties of the compound and the MS technique used, the molecular weight may be determined within an accuracy of one Dalton. The use of MS measurements will give sequence information where classical methods fail or may lead to ambiguous results as in the case of N-terminal blocked peptides, glycosylation or identification of the C-terminus. Next to this, MS is the ideal analytical method to support sample clean-up procedures and as a routine check for sample impurities of all kinds. As for sample requirements for MS, the samples should be free of non-volatile salts and the procedure typically requires between 1 ug and several nmoles, depending on the kind of analysis performed.

N is for Nucleus

For a crystal to grow, the system must be supersaturated, in non-equilibrium. But first, a stable nucleus must form. A stable nucleus is an aggregate of the macromolecule. A stable nucleus is an aggregate of such size, shape, and properties that it will enlist new molecules into it's growing surface faster than others are lost into solution.

N is for NIST/CARB BMCD

The NIST/CARB BMCD is a Biological Macromolecule Crystallization Database. The internet address for this freely accessible database is:

http://wwwbmcd.nist.gov:8080/bmcd/bmcd.html

The BMCD contains crystal data and the crystallization conditions, which have been compiled from literature. The current version of the BMCD contains 3547 crystal entries from 2526 biological macromolecules for which diffraction quality crystals have been obtained. These include proteins, protein:protein complexes, nucleic acids, nucleic acid: nucleic acid complexes, protein: nucleic acid complexes, and viruses.

Use the BMCD to see if your sample has been crystallized or to see if a related sample has been crystallized. Use this information to design crystallization experiments for your sample.

N is for Nuclease Inhibitors

Nucleases can be a real pain during the crystallization of nucleic acids. Here are some nasty things nuclease can do to your sample: Modification of sample size, charge, or hydrophobicity, partial or total loss of activity, or utter desctruction of the sample. Traces of nuclease can be difficult to detect even when overloading electrophoresis gels and can obviously cause sample damage during purification, concentration, and storage of samples. What is one to do? Well, one can include a nuclease inhibitor in the prep or sample to protect the sample from ribonuclease and deoxyribonucleases. Inhibitors of nucleases include RNasin (from Promega), ribonucleaoside-vanadyl complexes, and DEPC. Inhibitors of deoxyribonucleases include DEPC and chelators such as EDTA or EGTA.

O is for Osmium

Osmium is a good reactant for ribose moieties and the 3' terminus of RNA for heavy atom derivatives.

O is for Organic Solvents

The most popular volatile organic solvents used in biological macromolecular crystallization have been ethanol, acetone, isopropanol, tert-butanol, 1,3-propanediol, acetonitrile, DMSO, methanol, and 1,3-butyrolactone. Organic solvents can be utilized as a primary precipitant (buffered or unbuffered), as a secondary precipitant in the presence of salt or polymer (primary precipitant), or as additives. The most popular nonvolatile organics have been MPD and 1,6-hexanediol. Organic solvents act as precipitants by lowering the chemical activity of water. This means they steal water molecules from biological macromolecules in solution, through a process of hydrogen bonding. This in turn reduces the dieletric constant of the solution. Current popular thought is that organic solvents should be used at low temperatures (4°C or lower) and at the lowest possible ionic strength, keeping in mind to include whatever is necessary to stabilize the sample (buffer, divalent cations, etc.).

P is for Protease Inhibitors

Proteolytic modification of proteins can be a tool for making small active fragments of proteins, which might have enhanced solubility characteristics compared to the native protein, which in turn might make the protein more amenable to crystallization.

However, proteases can also be trouble makers when they are uninvited guests to a protein sample. When protease contamination can be a problem, one can consider adding a protease inhibitor to prevent cleavage of the sample by these nasty proteases. Protease contamination can occur when these nasty beasts are carried over from isolation and purification of the sample from a natural source or expressed proteins. Also, if your lab is situated in an area (on the same floor, building, etc.) where microbial research, plant research, or other work involving the possible generation of fungal and bacterial organisms is possible, then one might consider adding protease inhibitors to the sample for protection. Why? The presence of fungal or microbial contamination in your sample, reagents, or crystallization related plates, capillaries, etc. can lead to growth of such organisms with subsequent release of proteases from these organisms so they can use your innocent little sample for food. Some crystal growers like to include sodium azide or thymol in all their reagents and sample as a deterrent to microbial growth, which prevents the possibility of microbial agents growing and secreting proteases into the sample solution. But sodium azide and thymol can sometimes bind the sample, are toxic, and in some cases do not live well with heavy atoms so some feel it is not wise to simply include these agents as a multi-vitamin in the crystallization cocktail. Rather, clean workspace, sterile filtered samples and reagents, sterile pipet tips, and good technique go a long way to preventing microbial contamination. Well, back to the P for Protease Inhibitors. Here are a few protease inhibitors and their targets.

Protease:	Metalloproteases
Inhibitor:	Chelators like EDTA and EGTA, bestatin, amastatin, thiol derivatives, hydroxamic acid, phosphoramidon.
Protease:	Aspartic Acid Proteases
Inhibitor:	Pepstatins and statin derived inhibitors.
Protease:	Cysteine Proteases
Inhibitor:	Thiol binding reagents, peptidyldiazomethanes, epoxysuccinyl peptides, cystatins, peptidyl chloromethanes.
Protease:	Most
Inhibitor:	DEPC
Protease:	Serine Proteases
Inhibitor:	Trypsin inhibitors, leupeptin, boronic acids, cyclic peptides, DIFP, PMSF, Pefabloc, aminobenzamidine, 3,4-dichloro isocoumarin, chymostatin.

Q is for Quintillion

In the USA and France, quintillion is the number 1 followed by 18 zeroes. In the UK and Germany, it is the number 1 followed by 30 zeroes. Use this term to impress your lab mates, as in "Hey, have you tried my new screen with a quintillion different conditions?" Just think of it, a screen with a quintillion conditions. Gotta get a hit with that one. Problem is, most of us are lacking a quintillion mg of protein...

Q is for QELS (Quasi Elastic Light Scattering)

Another name for DLS (see D).

Q is for Quiet

Vibration has been reported to lead to excessive nucleation and crystals of questionable quality. It is often suggested that crystallization experiments be incubated in a location with minimal vibration. Avoid cabinets that are frequently opened and closed, or countertops where equipment such as centrifuges or vortexes live. Incubators can be another sore spot for vibration, especially poorly insulated incubators with compressors that are not well isolated.

R is for Reducing Agents

Reducing agents are substances that cause other chemical species to be reduced or gain electrons. In order for reducing agents to cause the gaining of electrons on some other chemical species, they must undergo oxidation. Therefore reducing agents undergo oxidation when they do their job.

Dithiothreitol (DTT), beta-mercaptoethanol (beta-me), and Tris(2-Carboxyethyl)-Phosphine Hydrochloride (TCEP HCl) are sulfhydryl protective reducing agents. Reducing agents are typically used to prevent the oxidation of free sulfhydryl residues (cysteines) in the protein. Such oxidation can lead to non-specific aggregation of the sample, sample heterogeneity, inactivity, or denaturation of the sample. In a typical crystallization experiment, reducing agents are used in the concentration range of 1 to 10 mM in the crystallization drop.

Beta-me has one sulfhydryl group and is the weakest of the three reducing agents discussed here, lasting perhaps two to three days. The supply of beta-me should be replenished every two to three days in the crystallization experiment to maintain the effectiveness of the reducing agent. Since beta-me is volatile, it can be added to the reservoir of vapor diffusion experiments for diffusion into the crystallization drop.

DTT has two sulfhydryl groups and lasts about three to seven days in a typical crystallization experiment. DTT is not a strong volatile like beta-me (although it does possess a strong odor) and should be added directly to the crystallization drop when possible. Another consideration when working with DTT is to use the microdialysis method for crystallization since DTT can be added to the dialysis solution to replenish the supply of reducing agent.

TCEP HCl is stronger than both beta-me and DTT, lasting about 2 to 3 weeks in a typical crystallization experiment. TCEP hydrochloride can acidify the crystallization solution. Like DTT, TCEP HCl needs to be added directly to the crystallization drop, hence, microdialysis is a consideration.

Beta-me, DTT, and TCEP HCl can behave differently. Like all additives, if you find a class of compounds has an effect on sample stability or crystallization, then screen a variety of compounds in that class to see which one is best for your application. What we are trying to suggest is that like all additives, one might consider evaluating all three reducing agents to see which one works best for your sample.

There have been reports where reducing agents have been used as successful crystallization additives where there were no free sulfhydryls in the sample.

Reducing agents can bind metals and trace metal compounds, inactivating the reducing agent and the metal. This can make heavy atom derivatization in the presence of reducing agents, difficult and frustrating. EDTA can be added to the crystallization experiment to avoid inactivation of the reducing agent by metals. Keep in mind that if your sample needs metals for activity or stability that EDTA will keep metals from your sample.

When working at an alkaline pH, beta-me and TCEP HCl are more stable than DTT. TCEP HCl is more stable at acid pH than DTT.

DTT reduces nickel ions and can cause problems when purifying His-tagged proteins. To avoid this complication, try beta-me or TCEP HCl as a reducing agent instead of DTT when purifying His-tagged proteins.

L-cysteine is also a reducing agent. It's usefulness in crystallization is limited since it likes to form small hexagonal plate shaped crystals. L-cysteine can be a useful crystallization additive, but keep those pesky hexagonal plates in the back of your mind when working with L-cysteine.

If oxidation of the sample is expected or anticipated, reducing agents should be present during the preparation of the protein (when possible) and should be included, added, or replenished during the final preparation of the sample for crystallization. In vapor diffusion experiments, the reducing agent can be included or added to the crystallization reagent in the reservoir to minimize or prevent dilution of the reducing agent in the sample drop.

When deciding on the appropriate concentration of reducing agent for the sample, consider the number of free sulfhydryls in the sample as well as sample concentration. More free sulfhydryls and higher sample concentration mean that one should consider using higher concentrations of reducing agent.

Arsenical compounds are not compatible with reducing agents. Cacodylic acid, or sodium cacodylate is an arsenical compound and popular crystallization buffer and is not compatible with reducing agents. Other compounds not compatible with reducing agents include ammonium nitrate, hydroperoxide, potassium perchlorate, sodium nitrate. Check the Material Safety Data Sheet (MSDS) for these reagents for specifics about the incompatibilities of these chemicals with reducing agents.

S is for Sample Preparation

Preparing the Protein for Crystallization

Lyophilization

Avoid lyophilization. Even though there are many examples of proteins which crystallize after lyophilization (lysozyme, thaumatin, hemoglobin), lyophilization is to be avoided when possible. If the protein is lyophilized, it needs to be dialyzed before crystallization. Dialyze the protein against deionized water or a stabilization buffer before crystallization. Dialysis will remove non-volatile buffers and other chemicals which may have been present before lyophilization.

Ammonium Sulfate Precipitation

Avoid using ammonium sulfate precipitation as a final purification and/or concentration step. It is often very difficult to completely remove all the ammonium sulfate by a desalting column of dialysis. The remaining trace amounts of ammonium sulfate can interfere with crystallization screening results and create reproducibility problems. It is not uncommon for trace amounts of ammonium sulfate in the sample to cause precipitation or excessive nucleation in screen conditions containing polyethylene glycol and salt.

Batches

Avoid combining different purification batches for crystallization trials. Purification conditions and procedures are never identical so each batch should be screened separately.

Profile the Protein

Ideally, you will purify your own protein, but this is not always reality. So, it is always a good idea to characterize your protein before beginning crystallization experiments. Profiling your protein before crystallization can often provide valuable clues during screening and optimization of crystallization conditions. Assays to seriously consider:

- SDS-PAGE
- Native PAGE or
- Dynamic Light Scattering
- IEF (Isoelectric Focusing) Gel
- Mass Spectroscopy

The results of these assays can:

- Determine the purity of the sample
- Determine the homogeneity of the sample
- Identify batch-to-batch variations
- Identify stability problems with the sample

How Pure?

How pure should the protein sample be for crystallization trials? As pure as possible. That's some answer, is it not? Integrating common sense into the question, we might arrive at the following answer. For initial screening, the sample should be at least 90 to 95% pure on a Coomassie stained SDS-PAGE. Finally, it does no harm to screen an "impure sample" as one can always perform further purification. Remember, crystallization used to be considered a very powerful purification tool (and still is!).

If the initial screen does not produce crystals, any promising results, or it becomes next to impossible to improve crystal quality during optimization, one should consider further purification of the sample.

Storing the Sample

Most proteins can be stored successfully at 4°C or -70°C.

Check with the person preparing the protein or compare your protein to a similar protein in the literature for best storage temperature.

Ideally, one should assay the activity and stability of the protein before storage and then later on at various points in time to determine the sample storage stability.

Repeated freezing and thawing of the sample should be avoided. Aliquot the sample into multiple small microcentrifuge tubes. Make the aliquots small enough so that the entire aliquot can be consumed in the experiment after thawing.

Sometimes people like to add glycerol (10 to 50% v/v) to help proteins better tolerate freezing. Avoid this if possible since it is often difficult to remove glycerol by dialysis or filtration. The presence of glycerol is a crystallization variable. Glycerol can behave as a precipitant, an additive, or cryoprotectant and therefore can influence the outcome of a crystallization experiment.

In general, it is better to store proteins more concentrated than diluted. When too dilute, adsorption of the protein onto the storage container can lead to significant losses. However, precipitation can sometimes be a problem when the protein is stored too concentrated.

Label samples clearly with the sample identification, batch identification, and date of storage. Small cryo labels can be very useful here. Color coding samples can be a nice organization tool. For the sake of easy organization and identification, it is sometimes more convenient to nest samples. For example, store batches of small microcentrifuge tubes in 10 ml or 50 ml centrifuge tubes and organize them by batch or sample.

Sample Handling

Be nice to your protein. Remember that proteins make an excellent food source for microbes. Protect your sample from microbes by storing the protein at less than 4° C and not leaving the sample for extended periods of time at room temperature.

When thawing a sample or mixing a lyophilized sample into solution do not shake or vortex the protein. Avoid foaming the sample. Foam can be a sign of denaturation.

Allow the sample to equilibrate to the temperature where the crystallization experiments will be set up and/or incubated before setting the experiment.

The field of crystal growth is full of opinions and controversy. There are several opinions on what should be done with the sample just prior to setting the crystallization experiment. Let's have a look at those opinions.

Some like to filter the sample through a 0.2 micron (or smaller, but be sure to compare the MW of your sample to the pore size of your filter so as not to stick your sample on the filter) pore size filter into a sterile container. Filtration can remove microbial contamination (but not the proteases) as well as sample aggregation. Turbid sample solutions with lots of precipitate should be solubilized or centrifuged before filtration to avoid the ugly experience of sticking the sample to a filter membrane. Use filters with the smallest possible dead volume to minimize sample loss. Some of the centrifugal microfilration devices are certainly worth consideration. Before filtering the sample, wash or flush the filter with a small amount of the sample buffer / storage solution before filtering the sample. This will test the filter for compatibility with your sample buffer and remove any trace glycerol which can sometime be present from the manufacturer. If possible, test filter a small aliquot of the sample, and measure the activity / OD before filtering the entire sample. Do this to test the adherence of the sample to the filter media. Read and follow the instructions supplied before introducing the sample to the filter.

Some like to centrifuge the sample. Centrifugation removes large sample aggregates and amorphous debris. Post centrifugation views can provide a visual clue of aggregation/precipitate for seemingly clear solutions. Following centrifugation, use only the supernatant for crystallization trials.

Others prefer to avoid filtration or centrifugation before setting crystallization experiments. One view is that the presence of amorphous material or aggregates can enhance the changes for crystallization be acting as nucleants.

To Azide or Not

Sodium azide (NaN3) is an anti-microbial preservative that is sometimes used to protect samples and crystallization reagents from microbial contamination. Sodium azide is toxic and should be handled with care. Typical sodium azide concentrations are 1 mM or if you prefer % measurements, between 0.02% and 0.1% w/v.

If you choose to use sodium azide remember that:

- It is toxic to humans as well as microbes.
- It is an inhibitor for some proteins and may become an unintentional ligand for your sample.
- It can interfere with heavy atom derivatization.
- Some metal azides are explosive.
- There are reports where eliminating sodium azide from the experiment improved crystallization.

Alternatives to Sodium Azide Include Thymol and Thimerosal.

A final alternative to the use of antimicrobials is the use of proper sterile technique and materials. Sterile filter all samples and reagents into sterile containers. Store samples and reagents at 4°C or lower. Use sterile pipet tips. Keep your work area clean. Develop a sterile technique with your crystallization setups. With common sense, sterile reagents and sample, good technique, and sterile pipet tips, one can successfully avoid the use of chemical antimicrobials in the crystallization lab.

Record Keeping and Organization

It is prudent to write down and hold onto detailed notes concerning the purification, storage, and handling of the sample. It is obvious that one should also maintain records of crystallization trials which should include:

- Sample information
- Name of sample
- Sample identification (batch, storage location, storage temperature, etc)
- Sample buffer composition, additives, ligands, etc.
- Sample concentration
- Crystallization experiment information
- Method
- Drop size and composition
- Reagent composition
- Temperature
- Date
- Person performing experiment

Although it may seem trivial, a little AR, and excessive, it is reasonable to write down anything that could become a crystallization variable.

Maintaining accurate and complete records of experimental observations is obviously important and will be covered in more detail elsewhere. In general, try to use both descriptive and quantitative comments when developing crystallization records.

Maintain a clean and well organized workplace for your crystallization setups. Cleanliness will help to prevent chemical, microbial, and miscellaneous contamination. Organization will prevent errors and save time.

Questions to Ponder About the Sample

- Does a similar sample exist and has it been crystallized?
- Does the sample contain free cysteines?
- Does the sample contain additives such as sodium azide, ligands, inhibitors, or substrates?
- Is the protein glycosylated?
- Is the protein phosphorylated?
- Is the protein N-terminal methylated?
- At what temperature is the protein stable?
- How does sample solubility and stability change with temperature?
- How does sample solubility and stability change with pH?
- Does the sample bind metals?
- Is the protein sensitive to proteolysis?
- What class of protein am I working with (antibody, virus, enzyme, membrane protein)?
- What have been the most successful approaches with my class of protein?
- What is the source of the sample?
- How was the sample purified and stored before it arrived into my hands?
- What is in the sample container besides the sample (buffer, additives, etc.)?
- Is the sample pooled purification aliquots or a single batch?
- How much sample do I have and how much more is available?
- How pure is the sample?

- How homogeneous is the sample?
- Does anyone possess any solubility information on this sample?
- What is unique about this protein?
- What is necessary chemically and physically to maintain a stable, active sample?

T is for Temperature

Temperature can be a significant variable in biological macromolecule and small molecule crystallization[1-5]. Temperature often influences nucleation and crystal growth by manipulating the solubility and supersaturation of the sample. Temperature has also been shown to be an important variable with phase separation in detergent solutions during membrane protein crystallization[7].

Control and manipulation of temperature during the screening, optimization, and production of crystals is a prerequisite for successful and reproducible crystal growth of proteins with temperature dependent solubility. Christopher et al.[5], testing 30 randomly chosen proteins, found 86% demonstrated a temperature dependent solubility and suggested that temperature induced crystallization could be a generally useful technique. Temperature was shown to affect quantity, size, and quality of the crystals, as well as sample solubility and preliminary crystallization data.

One advantage of temperature is that it provides precise, quick, and reversible control of relative supersaturation. Using temperature in addition to standard crystallization variables such as sample concentration, reagent composition and concentration, as well as pH, can increase the probability of producing crystals as well as uncover new crystallization conditions for a sample. Additional crystallization conditions may uncover reagent formulations more amicable to heavy atom derivatization, cryoprotection, and optimization or at least offer options. Temperature is amenable to control and can be used to carefully manipulate crystal nucleation and growth. This control can also be used to etch or partially dissolve, then grow back the crystal in an attempt to improve crystal size, morphology, and quality or assist with seeding. Temperature control is noninvasive and can manipulate sample solubility and crystallization without altering reagent formulation.

Typically, crystallization screens and experiments are performed at room temperature and possibly 4°C. A reasonable range of temperature to screen and optimize for protein crystallization is 4 to 45°C and some proteins have been crystallized at 60°C (glucagon and choriomammotropin). Temperature incubations above room temperature should be monitored closely for evaporation from the drop and reservoir. A 2 µl hanging drop vapor diffusion experiment at 37°C can evaporate in as little as 48 hours depending upon the plate and quality of seal. Microbatch under paraffin oil can minimize evaporation problems. In the case of room temperature incubations, temperature control and stability are often minimal since the experiments may be left in the open room. In an open room, temperature fluctuations may be significant, especially over a 24-hour period and on weekends when thermostatic control of the room environment can fluctuate 10° or more. Incubation at 4°C and other temperatures are often more stable since the incubation is performed in some type of incubator. Another source of temperature fluctuation occurs while viewing experiments. The light microscope is a heat source and extended viewing can significantly alter the temperature of small drops. Quick, efficient viewing can minimize temperature changes. Also, remember to turn off the light source when leaving plates on the stage in one position for more than a few seconds.

While controlled temperature can be important for consistent results, temperature fluctuation can be useful in obtaining high quality crystals by screening a larger range of crystallization conditions[8] since for a sample with temperature dependent solubility, changes in temperature can equate to changes in a crystallization reagent condition. Hence, a sparse matrix screen takes on a new dimension when screened at multiple temperatures, or ramped over several different temperatures over a period of time.

How does one test for the effect of temperature and temperature dependent solubility without consuming a lot of sample? One solution is to set a single crystallization screen at one temperature, allow the experiment to incubate for a week, record the results, and then move the plate to another temperature. Allow the experiment to incubate for a few days to a week at the new temperature and record the results. If one notices change in solubility (i.e. clear drop turning to precipitate, or precipitate turning to clear drops) between the two temperatures, then the sample has temperature dependent solubility and temperature should be explored as a crystallization variable.

Temperature gradients can be used for screening and optimization of proteins with temperature dependent solubility. For screening, set the experiment at one temperature, allow the experiment to equilibrate and then slowly change the temperature to a second temperature. In general, ramp the temperature so that the sample is exposed to an increase in relative supersaturation as the temperature changes over time. In other words, ramp from high to low temperature if the sample is more soluble at high than low temperatures. A temperature gradient or ramp allows one to slowly approach temperatures where a sample may have a decrease in solubility with a corresponding increase in relative supersaturation. Published examples of temperature gradient or temperature ramp crystallization include elastase[9] (25 to 20°C gradient), alpha-amylase[10] (25 to 12°C gradient), and insulin[11] (50 to 25°C gradient).

To demonstrate how screening temperature could affect and enhance the results obtained from a preliminary crystallization screen, the Hampton Research M6 Mini Temperature Incubator was used to screen 4 different temperatures. Using glucose isomerase and Crystal Screen, sitting drop vapor diffusion experiments were set using Cryschem™ plates at 4, 15, 25, and 37°C. Drops were observed daily and the results were quite interesting. Glucose isomerase crystallized in 19 conditions at 25°C, 23 conditions at 15°C, 28 conditions at 4°C, and 12 conditions at 37°C. A similar approach with Trypsin, yielded crystals in 8 conditions at 15°C, 4 conditions at 25°C, and 7 conditions at 32°C. In the case of Trypsin, a single set of Cryschem plates were set and the plates simply moved from one temperature to another over a period of a week, scoring results before each temperature change.

Temperature Tips

- In high salt, proteins with normal solubility will be more soluble at cold than at warm temperatures.
- In low salt, proteins with normal solubility will be more soluble at warm than at cold temperatures.
- Proteins with normal solubility will precipitate or crystallize from a lower concentration of PEG, MPD, or organic solvent more slowly at low than at high temperatures.

- Diffusion rates are less and equilibration occurs more slowly at low than at high temperatures. Crystallization may occur more slowly at low than at high temperatures.

- Temperature effects can be more pronounced at low ionic strength reagent conditions.

- Do not use the appearance or non-appearance of crystals at various temperatures to gauge the effectiveness of temperature as a crystallization variable. Rather, use the difference in the solubility at different temperatures to gauge the effect temperature has on sample solubility. If an effect is observed, explore temperature as a crystallization variable.

- Temperature can affect different crystal forms and growth mechanisms[12].

- When incubating experiments below and above room temperature and viewing experiments at room temperature, condensation can be a problem. To minimize and avoid condensation with vapor diffusion experiments, stack a dummy plate with reservoir filled with water and sealed, at the bottom and top of the stack of plates. This will slow the temperature change in the sandwiched plates and minimize condensation.

- The microbatch method works well for temperature exploration. In a traditional microbatch experiment, the relative supersaturation of the system does not change since, in theory there is no vapor diffusion. However, if the sample exhibits temperature dependent solubility, temperature can be used to manipulate sample solubility in a microbatch experiment. Another plus of using microbatch is the lack of condensation while viewing the experiment. Covers of microbatch plates can be removed for a clear view.

- Condensation with a hanging drop can mean alteration of your drop when the condensation mixes with the drop. Condensation with a sitting drop can mean there will be no mixing of the condensation with your drop, unless the condensation falls into the drop. Moral, sitting drop has less chance of mixing with condensation.

- To dry up condensation, add a small amount of concentrated salt solution to the reservoir. Keep in mind this might also dry your drop a bit.

- Ideally, one should set the experiment at the eventual incubation temperature and all reagents, samples, and plates should be equilibrated to the incubation temperature. This is a reality for room temperature and 4°C setups for those of us with cold rooms. For the rest of us, we can set the experiment at room temp and then toss it into the incubator. Or, for 4°C setups, one can cheat. Simply incubate the reagents, sample, plates, and slides in the refrigerator before setup. During the setup, place materials in a tray full of ice. Maintain the plates on ice during the setup. Seal and move smartly to the 4°C incubator.

- Nucleic acid temperature stability allows one to examine temperatures between 4 and 35°C.

- Increasing temperature increases the disorder of reagent molecules. Varying the temperature of a crystallization experiment can manipulate sample-sample as well as sample-reagent and reagent-reagent interactions. Such manipulations may have an impact on interactions that control nucleation and crystal growth. In addition, such interactions may have an impact on crystal packing as well as the termination of crystal growth. Hence, temperature can impact nucleation, growth, packing, and termination.

- Temperature can be a habit modifier and change the crystal lattice. For example, at temperatures below 25°C and in the presence of sodium chloride and acidic pH, the tetragonal form of lysozyme is favored. Under similar reagent conditions above 25°C, the orthorhombic form is favored[13].

- The preparation of heavy atom isomorphous derivatives can depend upon the temperature of the experiment. In most cases, it seems the soak temperature is the same as the crystallization temperature.

U is for Units

Molarity is the number of moles of solute per liter and in represented as M, such as 3.0 M ammonium sulfate. Molarity is the ratio between the moles of dissolved solute (solid stuff) and the volume of solution (liquid stuff) in liters. The accepted volume of the solution is 1 L, so a 1M (molar) solution would be 1M = 1 mole of solute/1 L solution. Molarity is a way of determining the concentration of a solution. Dilute solutions are typically expressed in terms of millimolarity (mM) where 1 mM = 0.001 M. Typically, in crystallization we are asked to make something like a 3.5 M solution of ammonium sulfate. To do this we need to know the molecular weight of ammonium sulfate (132.14 g/mole), the volume of solution to make (let's make 500 ml or 0.5 L), and the desired concentration (3.5 M doh!). Then we calculate:

$$\#\ \text{grams required} = (3.5\ \text{mole/liter})(0.5\ \text{liter})(132.14\ \text{g/mole}) = 231.25\ \text{g}$$

So, we then weigh 231.25 g of ammonium sulfate and add deionized water to dissolve the ammonium sulfate and then adjust the final volume to 0.5 liter (500 ml). Do NOT add 500 ml of water to 231.25 g of ammonium sulfate. Ideally one should use the most precise measuring instrument possible such as a volumetric flask. The less desirable instrument would be a graduated cylinder and the least desirable would be a beaker.

Molarity is typically used as a concentration unit for salts 1,6-hexanediol, detergents, and some additives.

% w/v (percent weight/volume) is often used when formulating high molecular weight polyethylene glycols which begin life as solids as well as some additives. % w/v is the weight of a solute in a given volume. % w/v = gram per 100 ml. For example, 50% w/v PEG 3350 is 50 g of PEG 3350 in a final volume of 100 ml and

NOT 50 g of PEG 3350 plus 50 g of water. This means weigh 50 g of PEG into a graduated cylinder or volumetric flask and bring the final volume to 100 ml with water. To clarify, in order to make a 500 ml of a 30% w/v solution of PEG 8000, simply weigh 150 g of PEG 8000 and bring it to a final volume of 500 ml in deionized water. Often the mistake of adding 150 g of PEG 800 to 350 ml of water is thought of as a 30% w/v solution. This is a huge no-no and makes one look like a lab rookie. Get it right and look cool.

%v/v (percent volume/volume) is often used when formulating liquid, low molecular weight polymers (PEG 400), organics (MPD), and organic solvents (iso-propanol) into stock solutions. % v/v is the volume of a solute in a given volume and NOT a volume plus a volume. For example, a 50% v/v iso-propanol is 50 ml of iso-propanol brought to a final volume of 100 ml with water and is NOT 50 ml of iso-propanol plus 50 ml of water. Once again, the latter is a big no-no and makes you look like a Homer.

Additional comment regarding % w/v and % v/v. Do not ask someone "What is your definition of % w/v?". There is only one correct definition. Therefore all other definitions are wrong. Keep life simple and use only one definition of % w/v and % v/v. The correct definition. There is only one correct way to make these solutions. There is one occasion where one can ask the question, "What is your definition of % w/v?" and this is when someone new enters the lab and you want to check them out and see if they know anything about growing crystals or you want to steal your buddy's crystallization reagents but you want to be sure they make them properly before you risk getting into trouble for stealing junk solutions.

% saturation is the concentration of material in solution as a percent of the maximum concentration possible at the given temperature. A saturated solution is one where there is equilibrium between undissolved solute and dissolved solute. To make a saturated solution, a salt is added to water and often warmed to enhance solubilization. Complete dissolution is desired. Upon cooling, some of the solute (salt) will crystallize out and leave behind a saturated solution. The actual concentration of a saturated stock depends upon the temperature of the solution. For example, at 0°C, 127.5 g of potassium iodide can be dissolved into 100 ml of water, but at 20°C, 144 g of potassium iodide can be dissolved into 100 ml of water. Therefore, depending upon whether the solution is kept at room temperature or in the cold, the concentration can be very different. % saturation is an old school way to make salt solutions for crystallization. However, since we often perform crystallization at different temperatures, the actual concentration in the bottle, reservoir, or drop can be very different. Plus, exact reproduction of a stock solution not only depends upon careful mass and volume measurement, but also temperature. Keep life simple, avoid reproducibility hassles and stick with M, % w/v and % v/v.

Mg/ml (mg/ml) is typically used to express or determine protein concentration. Oftentimes we like to whip up a batch of lysozyme to test a new or stupid crystallization idea or simply prove to ourselves that we can crystallize a protein (especially those of us working with kinases, membrane proteins, and other chewing gum macromolecules). To make a 20 mg/ml lysozyme solution we might weigh 20 mg of lysozyme and simply add 1 ml of buffer (20 mg plus 1 ml). However, others might weigh 20 mg of lysozyme and add 980 µl (0.98 ml) (20 mg in 1 ml). Same rough definition, but different concentrations of lysozyme. Might not make a difference unless you are trying to reproduce someone else's work and you want to be sure you are comparing apples to apples and not apples to oranges.

A final note on units. Knowing how to properly calculate, formulate, and document crystallization reagents is an excellent foundation for becoming a crystal Jedi master. Just the same, knowing how to properly calibrate and use an analytical and top loading balance and select the appropriate glassware for the job are often overlooked, yet important crystallization variables. Quality and consistency are big time crystallization variables so it is important to learn and master good lab technique. While nobody ever won a Nobel Prize for cooking, most Nobel Laureates can cook up a storm.

V is for Vibration

Vibration is often associated (in a crystallographers mind) with excessive nucleation. It is popular belief that the best crystals grow when there is NOT a significant source of vibration. It is believed this is particularly important during the optimization and production stages of crystallization. Hence, it is suggested that during optimization and production, one set crystallization experiments and avoid the burning curiosity to look at the plates every single day. Try leaving the setups alone during optimization and production.

Since vibration can lead to excessive nucleation, it seems one might want to move the plates some during screening. One typically does move plates during screening as it is typically recommended to view experiments each day for the first week and once a week thereafter until the drop dries out. Maybe we need to build vibrators into our screening incubators. Along the same line, it is sometimes observed that plates which have been sitting for some time, then viewed, often have crystals forming in the days following the latent observation. So perhaps one should consider giving the plates a Monty Python nudge-nudge or move them about to stimulate nucleation.

To avoid vibration, place plates in cupboards, cabinets, or incubators that are infrequently opened and closed. Installing hydraulic door dampers to prevent slamming doors or cupboards is one way to reduce vibration. Some incubators vibrate more than other units and peltier based heating and cooling incubators may be desirable from this perspective. However, some of the circulation fans in these units vibrate quite a bit, so be sure to check out the fan and even consider replacing it with a higher quality unit with less oscillation and vibration.

W is for Water

The role of water in protein crystallization is significant as protein crystals are highly hydrated. The amount of water in a drop or a crystal, the purity, the chemical composition, and how the water interacts with itself, the sample, and reagents are all critical variables in a protein crystallization experiment. Consistency is typically a good thing to keep in mind when trying to reproduce crystallization results. Being consistent with one's treatment, handling and use of water can be a important crystallization. Consider the source of water. One should use pure and fresh water for crystallization experiments. Type II analytical grade water with a resistivity of less than 18.2 MΩ-cm, with a total organic carbon (TOC) of less than 30 ppb and low bacteria count is a good source of water for protein crystallization. Purchasing and using a quality water purification system is one part of the water source equation. Different water systems and different methods of water purification produce different water. For example, glass distilled water typically has a pH of 5.5 while reverse osmosis and deionization systems typically produce water with a pH of 7.

Another part of the water equation is the proper use and maintenance of the water purification system. Carefully follow the manufacturer's use, maintenance, and service guidelines. Establish regular quality control practices to ensure the consistent quality of the water. Using a water purification cartridge beyond its expiration date or failing to clean the system on a regular basis can lead to water with higher resistivity as well as microbial contamination. Microbial contamination can change the pH of the water as well as expose your sample to proteloytic modification. Use fresh water. Purified water is deionized and can leach zinc, lead, copper, iron, aluminum and other substance from glass or plastic storage containers. Purified water stored in plastic containers for several weeks has nearly the same level of TOC as tap water.

Use fresh, pure water for your crystallization experiments. When having trouble reproducing experiments, consider water, the difference in purity and the difference in source as potential crystallization variables.

X is for Xenon

Xenon is a noble gas that binds to specific sites in a macromolecule. Xenon-protein complexes can often serve as heavy atom complexes for MIR structure determination. Heavy atom derivatives of protein crystals can be produced by pressurizing native crystals with xenon gas. In the vast majority of cases, the modification of the mother liquor to determine soaking conditions is avoided since the crystal and mother liquor are simply placed in a chamber pressurized with xenon gas. Another advantage of working with xenon is that it interacts weakly with a protein so isomorphism of the derivative with the native crystal is high. Also, the number of binding sites as well as the binding occupancies can often be changed by altering the pressure of the xenon gas. Xenon binding sites often differ from heavy metal binding sites so it can be useful to try xenon when traditional heavy atom soaks fail. Xenon binding is often reversible so if one has very few crystals, the same crystal could be used for heavy atom soak.

The interaction between xenon and the protein is typically confined to weak dispersion forces and does not involve electrostatic interactions. Therefore, xenon should bind to different locations of the protein compared to most other heavy atom compounds. The weakness of the interaction between xenon and the protein makes it unlikely that xenon will interfere with crystal contacts. Xenon derivatives usually show good isomorphicity with the native crystal, resulting in high phasing power.

Xenon seems to have little or no effect on the pH or ionic strength of the mother liquor. The weakness of the interactions between xenon and proteins requires a significant xenon concentration in the crystal's mother liquor to enforce sufficient occupation of a potential binding site so most uses of xenon reported in the literature make use of high pressure equipment for xenon derivatization. At this time is appears cryocooling does not alter the protein's xenon binding properties.

Xenon derivatization can be performed at room temperature and data collection with xenon derivatives can be performed at room temperature using specially made pressure cells and capillaries or at cryogenic temperatures using CryoLoops.

Another application of xenon in protein crystals is the crystallographic imaging of disordered areas of lipids or detergents in crystals of membrane proteins.

Y is for Yummy

Protein samples are yummy treats for microbes such as bacteria, yeast and fungus which secrete proteases that like to chop your sample into tasty bites, ruining your crystallization setup. These same microbial menaces also like to dine on polymer based crystallization reagents such a polyethylene glycols and even buffers. So even if the bugs and their secreted proteases do not chop your sample into bits, they can degrade reagents, alter the pH of the solution, or generate chemical species which can influence crystallization and even make reproducing conditions a pain in the tush. To prevent or at least minimize your sample and reagents from becoming Sunday Crystallization Brunch for microbes, consider the following suggestions:

Sterile filter the sample into a sterile tube using a 0.2 micron filter before setup to remove microbes. Do not leave the sample on the bench at room temperature for extended periods. Store unused sample appropriately (4, -20, or -80°C; only you know best). Those of you working with engineers, physicists, computer scientists, or folks from outside the life science field, take a moment to realize that quarks, gluons, hard drives and other physical things these folks are used to handling do not support microbial growth. Take a little time to help these crystallization rookies understand what happens to samples left on the bench for a day or three and the significance of keeping things clean to prevent microbial (as well as chemical) contamination. Case in point – Caller: "My lysozyme stock that was growing crystals no longer grows crystals." Tech Support: "Where are you storing the lysozyme when it is not being used?" Caller: "Same place as the reagents." Tech: "Which is?" Caller: "On the bench (i.e. room temperature)." Tech Support: "For how long?" Caller: "Oh, not long, maybe a few days, a couple weeks at the most". Hey, nothing wrong with these types of questions. We all gotta learn some time. Just be sure and help that engineer, computer scientist and new post doc from a physics lab who is helping you with your new AFM machine or testing the high throughput robot, to understand proteins are food for microbes. Who knows, maybe they will help you with the next Windows update installation.

Sterile filter water into a sterile container before formulating crystallization reagents that cannot or should not be filtered (detergents, gels, and some high molecular weight polymeric agents too big for filtering).

Sterile filter (0.2 micron pore size) buffers, salts, polymers, and diluted organics into sterile containers. Sterile containers such as polypropylene or PETG plastic are readily available today and are cost-effective, time-saving alternatives to glass and autoclaving.

When using a stock that has been sitting about for more than a couple of weeks, give the bottle a swirl and look for signs of microbial growth such as a settle, faint white, off white or yellow to brown precipitate. Sometimes slightly precipitated salts will resemble microbial growth to the untrained eye. To help differentiate precipitate from microbial growth, try warming the solution in your hands for 5 to 10 minutes. If the material disappears it might well be precipitate. Microbial growth will not dissolve. Although we are not endorsing the sniffing of reagents, especially since some crystallization reagents can be hazardous, precipitates will not smell, while microbial growth will often stink.

Use sterile pipet tips when pipetting reagents, sample, and water into plates. Keep your filthy paws away from your pipet tips and do not touch pipet tips to the counter, your lab partner or other non-sterile items. If you set your pipet down it had better not have a tip on it or the tip will likely touch something non-sterile.

Keep crystallization plates in their sealed wrappers until just before use. This will prevent airborne microbes from setting up home in your crystallization plates. Most crystallization plates are not offered with a claim of sterility but most makers of these plates operate the injection molds in clean areas and package the plates straight out of the mold so there is little risk of contamination. Use them as is and put the worry into keeping them clean once the plate is out of the package.

If you do crystallization in a lab that also grows microbe bugs, especially fungal microbes, be especially careful as these airborne spore forming nasties can set up camp in crystallization plates quite easily.

Z is for Zeppenzauer

Microvolume crystallization by dialysis was first reported by Zeppenzauer in 1971 (Methods in Enzymology, ibid ref. 1. Vol. 22, page 253). The Zeppenzauer cells are homemade from capillaries with the ends of the tubes either covered with dialysis membrane or plugged with acrylamide, silica, or agarose gel. If covering the tube with a dialysis membrane, one can use small o-rings to secure the membrane over the tube. The capillary is then placed in an appropriate chamber with a volume of reagent sufficient to cover the ends of the tube.

Z is for Zinc

1 to 5 mM zinc (most frequently as zinc chloride or zinc sulfate) can be a useful crystallization additive and typically reduces the solubility of the sample. Zinc is not very soluble and can readily precipitate or crystallize out of reagents as higher concentrations.

Z is for Zero

Zero or “0” is often used to represent a clear drop when scoring crystallization experiments. While on the subject of zero or nothing, consider using -1 or some other more interesting and exciting score to represent a non-experiment. A non-experiment is a drop that has fallen off or a drop that was never pipetted (human or robot error). Better to use a non-experiment score such as -1 than a “0” since someone reading your scores might mistake a “0” as a clear drop.

Additives

Glycerol

Looking for yet another additive to try during optimization? Try Glycerol. Typical concentrations in the drop can range from 3 to 15%. Glycerol may limit non-specific aggregation and could be useful if you plan to use cryo techniques during data collection.

What Additive to Use

When trying to decide which additive might be useful during crystallization, try the following. If one has crystals and wants to try using additives to improve the crystal size or quality, go back to the initial crystallization screening plates. Review the plates, looking for conditions where neither precipitate nor crystals were/are observed. Now, review the results, looking for a common reagent ingredient present where no precipitate or crystals are found. For example, one might find that all drops with Isopropanol remained clear. One could then try adding Isopropanol to the current crystallization condition to see if it could improve the crystal size and/or quality. If one observes a difference in the crystal in the presence of isopropanol, then one might consider evaluating other additives in the class of alcohols such as Ethanol, Methanol, tert-Butanol and others. If one has no crystals, but plenty of precipitate, phase separation and clear drops, follow the above analysis and try adding the common reagent ingredient found in the clear drops to those drops which contained precipitate or phase separation. It is possible this agent could improve or at least manipulate sample solubility. The above tip was submitted from Jarmila Jancarik from the laboratory of Sung Ho Kim at the University of California, Berkeley. Thank you Jaru! When using this approach it might be reasonable to discern between concentration independent and dependent precipitation when trying to decide which agent to pursue as an additive. Try evaluating the concentration independent agents first and then look at the other agents if sample quantity permits. For example, if one observes precipitate in 15 to 40% PEG but not in 5 to 10% PEG, it might simply be a concentration. However, if one observes no precipitate in 45 to 60% v/v MPD, one could guess that MPD is a reasonable agent to evaluate as an additive.

Crystal Screen as an Additive Screen

Although Hampton Research does offer a specifically formulated Additive Screen™ (HR2-428), here is a tip submitted by the crystallography group at GSK (North Carolina) when one already has a sparse matrix screen or two laying about the lab. When screening additives, try adding 50 µl of each Crystal Screen™ reagent to 950 µl of the "best" crystallization conditions thus far, in order to see if any of the reagents in Crystal Screen might serve as good additives. Crystal Screen 2™ is an especially good kit for this technique since it contains numerous divalent cations such as Jeffamine® Reagent and a few other "novel" agents. Jeffamine® is a registered trademark of the Huntsman Petrochemical Corporation.

Benzalkonium Chloride

Try Benzalkonium chloride (Fluka 12060). This cationic surface active agent has been reported to be useful as a crystallization additive with membrane proteins and may be useful for soluble proteins. We've been using it in the drop between 1 and 3% w/v in water. Try a 10% w/v stock solution in water and dilute into the drop to 1-3%.

Sodium Thiosulfate to Prevent Intermolecular Disulfide Bridges

The presence of Thiosulfate in the protein solution was essential to promote crystal growth and to avoid the formation of unstable and weakly diffracting crystals.[1] This is likely to be a consequence of the intrinsic capability of the reduced thiol group of the active-site cysteine to form disulfide bridges, leading to the destabilization of the protein native structure. Sulfane sulfur-donor compounds such as $Na_2S_2O_3$ are likely to either keep the protein in the persulfurated form or to prevent intermolecular disulfide bridges leading to unfolding and aggregation.[2]

Dissolving Hydrophobic Additives into Oil

Try dissolving the small molecule additive into paraffin or silicon oil, and use this mixture to cover the sample drop. This can be used with sitting drop, vapor diffusion, or with microbatch under oil methods. The oil acts as a reservoir that may contain excess small molecules that (you hope) will be fed into the crystals.

Aggregation

Sample Buffer

Non-specific aggregation problems? Watch your sample buffer. The selection of an appropriate sample buffer/pH can often ward off aggregation problems.

Cryo

Cryo Buffer

We've had good success using the well solution directly as the foundation of a cryobuffer in several situations where crystals cannot be grown directly in the presence of cryoprotectant, and where crystals don't tolerate transfer to artificial mother liquors. The basic protocol is as follows: (1) Remove 100 µl of the well solution after crystals have grown; (2) Split this sample into two 50 µl aliquots; (3) Add 7.5 mg of Dextrose (Glucose) to the first aliquot and 15 mg to the second aliquot. Dissolve by gentle pipeting with a wide-bore tip. This will give two sequential well solutions that now contain 15% and 30% w/v Dextrose. If all the Dextrose won't go into the second aliquot, spin hard and remove the supernatant; (4) Transfer the crystal to aliquot number 1, equilibrate for 3 minutes, then to aliquot number 2, then freeze. We've had a few crystals that routinely crack or blow up when transfered to artificial mother liquor that behave well when transfered to well solution plus Glucose. We assume that there is some aspect of the crystal drop (pH, ionic tension, precipitant concentration) that is more effectively reproduced within the well than by separately prepared mother liquors. The nice thing about the protocol above is that you don't get much of a volume increase when dry Dextrose is dissolved in the well solution, so the components in the solution are not diluted. Finally, if you don't get a really good freeze, you can try to add about 5% v/v Glycerol to aliquot number 2, in addition to the 30% w/v Dextrose.

PEGs for Cryo

High molecular PEGs are also good cryoprotectants. If crystals are obtained from relatively high concentration of PEGs (e.g., 30% of PEG 3350), you can cryoprotect them simply by raising the concentration of the PEG a little bit (e.g., 40% of PEG 3350).

J. Appl. Cryst. (2006). 39, 244-251
Effects of cryoprotectant concentration and cooling rate on vitrification of aqueous solutions. V. Berejnov, N. S. Husseini, O. A. Alsaied and R. E. Thorne
Synopsis: Critical concentrations required for vitrification of aqueous solutions are determined for fourteen common cryoprotectants, for sample volumes ranging over four orders of magnitude and covering the range of interest in protein crystallography.

Mounting Thin Crystals

To mount very thin crystals onto CryoLoops™, first dip the nylon loop into 0.5% Formvar® solution (Fluka # 09819) to form a thin film. The film provides extra support for fragile crystals, and can result in much sharper reflections with just slightly higher background. To clean the loop, dip it in alcohol to dissolve the support. Two notes: (1) the technique works only for crystals grown without organic solvents; and (2) take precautions not to breathe vapor from the Formvar solution--the solvent is 1,2-dichloroethane. It is a standard support for electron microscopy grids.

The Potential Benefits of Cryogenic Data Collection

Reduced radiation damage.

Decreased thermal motion and disorder.

Potential for improved resolution.

Increased crystal lifetime.

Crystals can be stored and shipped.

Cryo continued...

Cannot Get Cryo to Work?

Try x-ray data collection at room temperature.

Evaluate other cryoprotectants. Try CryoPro™ from Hampton Research (HR2-132).

Try the idential procedure again with another crystal.

Vary the time and temperature of the crystal handling steps.

Try annealing.

Match the osmotic pressure of your cryoprotectant to the osmotic pressure of the reagent producing the crystal. Crystallization reagents with lower salt concentrations require a higher percentage of cryo reagent for cryo protection than crystallization reagents with higher salt solutions (Garman 1999). Osmolality tables (Weast 1988-1989) can be used to estimate the osmolality of reagents.

Cryo and Detergents

Be aware of the potential for detergent concentration mismatch between your mother liquor and the cryosolution. This particularly happens with vapor diffusion setups: there is a delicate balance of "free" detergent in the mother liquor versus the proportion of the detergent which is bound to the protein. Dropping a xtal into the cryosolution shocks the crystal with a bolus of extra free detergent. Hence, and counterintuitively, you may need to reduce the detergent concentration in the cryosolution to keep everything in balance. Try titrating down from 1% to even as low as 0.4% in the cryosolution. Under the conditions you are using, the CMC of bOG is suppressed below the usual 0.67% (w/v).

Also, the behavior of many of the alkyl glycoside detergents is very temperature sensitive. So be careful about the temperature of all the solutions you use.

R. Michael Garavito, Ph.D.
Submitted to CCP4 bulletin board February 2007
Edited by Hampton Research Corp.

Cleaning a CryoLoop™

Soak the CryoLoop in a 0.5-2.0% detergent solution for 15 minutes or more. To improve the action of the cleaning solution, try increasing the temperature of the solution. The use of ultrasonic or other agitation will further improve the cleaning action. Finally, lengthen the dwell time or increase the concentration of the solution.

Paper Wicks™ can be used for delicate scrubbing of the CryoLoop. Dip the end of the wick into a detergent solution or 2-Propanol, and gently clean the nylon CryoLoop.

Compressed air can be used to remove debris from a CryoLoop. Hold the tip of the air sprayer 3 inches from the CryoLoop and use gentle pressure (less than 25 psi).

Detergents

Detergent to Protein Ratio and Pea Type as Crystallization Variables

Ben-Shem et al (Acta Cryst. (2003). D59, 1824-1827) in the crystallization of higher plant photosystem I found the detergent to chlorophyll ratio had to be carefully optimized in all purification steps in order to produce ordered crystals. Crystals were produced in 22.5 mM MES-bis-tris pH 6.6, 0.5% v/v PEG 400, 8.1 mM Ammonium citrate, 6% w/v PEG 6,000. Crystals appeared in 2 to 3 days and matured in size within two weeks time, yet the loss of sharp edges and a degradation of diffraction quality was observed after an additional two weeks time. The initial diffraction resolution of 20 Angstrom was improved to 6 Angstrom through a seemingly tedious refinement of isolation, crystallization and cryo conditions. Again, the detergent to chlorophyll ratio as well as the pea type and growing conditions with adjustment of the preparation to seasonal changes were essential to improvement of crystal quality.

Amphophiles

When screening detergents as additives, be sure to evaluate small amphophiles such as 1,2,3-Heptanetriol, Benzamidine, Ethanol, Dioxane, 1,6-Hexanediol, Ethylene glycol, and Butyl ether for their ability to "manipulate" micelles.

Detergents, Oils and Microbatch

Detergents can be used successfuly as crystallization reagents in oil based microbatch experiments. Measurements by Barenda et al and Loll et al indicated no significant loss of detergent will occur by migration of the detergent into the oil.

Handling Crystals

Separating Twins

The following procedure for separating twins is reported in "Structural Basis for Double-Stranded RNA Processing by Dicer", Ian J. MacRae, Kaihong Zhou, Fei Li, Adrian Repic, Angela N. Brooks, W. Zacheus Cande, Paul D. Adams, Jennifer A. Doudna. Science 13 January 2006: Vol. 311. no. 5758, pp. 195 - 198.

Crystals of the protein Dicer grown at 18°C by vapor diffusion in hanging drops composed of equal volumes of protein solution (9 mg/ml) and reservoir solution (28% PEG-400, 0.1 M $MgCl_2$, 0.1 M NaCl, 5 mM TCEP, 1 mM DTT and 0.1 M MES, pH 6.5). Resulting crystals were pseudo-merhodrally twinned, producing an apparent spacegroup of P4222. Substituting $MgCl_2$ with $MnCl_2$ resulted in crystals that were macroscopically twinned. Individual crystals, which belong to the spacegroup P21212, were extracted by soaking the largest twinned crystals in reservoir solution containing 15% PEG-400 to weaken the twinning lattice contacts, followed by gentle mechanical prodding with a cat whisker. The resulting crystal shards were transferred back into full strength reservoir solution, cooled to 4°C for 1 hour and then cryo-cooled by plunging into liquid N2.

Handling Crystals continued...

14 Things to Say About Twins

1. Try additives.
2. Try DNA shuffling to introduce random mutations.
3. Try agarose gel crystallisation.
4. Try a new construct ("having tried everything else for 3 years before...").
5. Try to work on very small crystals and/or using a very small beam of a microfocus beamline at a synchrotron to isolate a single domain and get less twinning.
6. Destabilise the crystal to separate the two halves (when possible) as in http://www.sciencemag.org/cgi/data/311/5758/195/DC1/1
7. If the crystals are obtained with Mg exchange it to Mn.
8. Change in crystallisation pH.
9. Change in crystallisation temperature.
10. You can try switching proteins. Lysozyme usually does the trick.
11. Co-crystallisation with partner proteins/domains or with ligands.
12. "Hmmm. Who knows, eh?"
13. Change crystallisation setup (e.g., from microbatch to hanging drops).
14. Test crystals at room temperature as well: "(EBV protease) which became twins only upon freezing, at room temperature the crystals were untwinned (but resolution was much worse as well)".

Crystal Annealing

Macromolecular crystal annealing (MCA) can help overcome increase mosaicity associated with cryocrystallography (Harp et al 1998, 1999). One might consider annealing if diffraction is uncharacteristically poor after flash cooling. The process cycles a flash cooled crystal to ambient temperature and then to cryogenic temperature and requires no special equipment. The annealing process does not improve a poorly diffracting crystal suffering from molecular disorder. The annealing protocol assumes that adequate cryo protection is available or that the crystal may be flash cooled using an oil and that the crystal diffracts well. The crystal is flash cooled a cryo stream. In the MCA procedure, the crystal is removed from the cryo stream and placed in a large (300 microliter) volume of the optimal reagent/cryo/oil solution from which the crystal was originally grown/mounted. Cover this drop to prevent evaporation. Incubation time at room temperature is typically 3 minutes. Extended incubation times are okay, but shortening the incubation time can produce inconsistent results. MCA has been successfully reported for both small and large crystals as well as for crystals with low (30%) or high solvent (70%) content.

Other forms of crystal annealing, one termed flash annealing (Yeh and Hol 1998), the other termed annealing on the loop (Harp 1999), have been used successfully, especially on crystals with low (30%) solvent content. For flash annealing the crystals remain in the loop and on the mount. The cryo stream is diverted for 1.5-2.0 seconds, then reflash cooled for 6 seconds before repeating the process for a total of 3 rounds of rewarming and flash cooling. For annealing on the loop, a variable length of time for warming is used without multiple rounds of warming and reflash cooling. Warming time for cooling on the loop is determined by observing the crystal in the loop while the stream is diverted and waiting until the drop in the loop is clear before reflash cooling the crystal. Warming time is typically proportional to the size of the crystal. For the flash annealing and annealing on the loop methods one might carefully reduce the amount of liquid in the loop using a paper wick or micro wick as a variable to improve annealing results. But be careful not to let the drop dry too much. Finally, one might be prepared for the formation of ice on the crystal and loop when the stream is blocked. Ice can be removed with the delicate use of a paper wick or fiber.

In closing, one may attempt the quick annealing methods first, although the MCA seems to be more general.

Handling Crystals continued...

Minimizing Radiation Damage

Small molecules which behave as electron and free radical scavengers can be used for co crystallization and soaking to reduce radiation damage to the macromolecular crystal. Recommended scavengers include oxidized glutathione, nicotinic acid, 5,5'-Dithiobis(2-nitrobenzoic acid) (DTNB), and ascorbic acid. Typical scavenger concentration is 0.2 M in the original crystallization reagent. A quick (less than 20 second) soak can be used to introduce the scavenger to the crystal. Prepare fresh solutions (add solid material to crystallization reagent in plate well) just before the soak.

Microbatch Crystal Mounting Tips

Here is the compiled 'tricks of the trade' for microbatch crystal mounting from the CCP4B community. Rebecca Page, Brown University, September 2006.

Original Post to CCP4 community:
I find mounting crystals grown in microbatch drops difficult compared to mounting crystals grown out of sitting drops, primarily because of the oil layer. Do most people simply use the oil layer as a cryoprotectant? If not, do you typically try to remove the oil prior to transferring the crystal to a cryoprotectant? I'd like to compile 'tricks of the trade' for mounting crystals out of microbatch plates. Any advice would be helpful and I'll compile the list of responses and repost for the community.

Summary of responses:
Sorry if this sounds like a crazy suggestion, but sometimes the simplest things work. Did you try to mount the crystal directly on a loop and see if it diffracts? The oil can be cryoprotectant.
The setup would be:

1. Fish the crystal with a loop
2. Do not care if it comes across the oil layer and it retains the oil
3. Mount in the cryostream
4. Shoot x-rays and see if you have diffraction

If everything fails and you have few more drops of crystals and do not know how to freeze mount, here is another way you can try :- If you have few crystals in the drop under oil and the drop size (excluding oil!!) is few µl: add 10 µl of mother liquor (you can get the mother liquor conc. based on few trials; it should be few % more than the final conc. of the one you had used while setting up the microbatch, a decent start will be 5 % more), allow it to stand for few minutes. Then use the classical cappillary mounting method to suck the crystals slowly out and onto a cover slip. If possible try to remove as much as possible (you may not be able to remove everything) the halo of oil surrounding the drop on cover slip (using the same capillary watching under microscope to make sure you are not sucking out the crystals). The use of mother liquor (the 10 ul) is to basically to reduce the oil that come along when you suck the crystals, so if necessary you can use more µl's. Now quickly scoop the crystal with a loop and dip in the cryoprotectant and freeze it, in the usual way. This has worked for me, though it may need some more standardization depending on your case.

In one case I had crystals grown under paraffin oil in microbatch, which required 25% glycerol for cryoprotection. However, when I transferred them directly to the base condition + 25% glycerol, they would invariably break up. So I ended up picking up a crystal with a loop, pulling it through the oil, and putting it on a coverslip. Then I removed the surrounding liquid and quickly replaced it with 4 µl of base solution + 5% glycerol, observing the process under the microscope. The crystal seemed to hold up fine, and I then progressively replaced the solution with base condition + 10%, 15%, 20% and finally 25% glycerol. The resulting crystal froze nicely, and provided a 2A dataset. Any oil that was still around the crystal from the first transfer was probably completely removed by the cryo/washing steps, as other people have already described.

Handling Crystals continued...

Microbatch Crystal Mounting Tips...continued

We do the same, I prepare 2-3 drops of cryoprotectant on a microscope slide, draw the crystal through the oil and "wash" in successive cryo drops until I see no more oil coming off. Paraffin oil itself is mot a good cryo protectant, if you want to use paratone oil you can use the same procedure, or first get rid of the paraffin oil in artificial motherliquor drops, then tranfer to paratone.

I have very tough time mounting crystals from microbatch. Essentially, I was adding the cryoprotectant to the drop and then transferring crystals to another drop of cryoprotectant. Yet, I lost many crystals before successful mounting. At times, I tried to remove the oil layer and then add cryoprotectant, but it was always difficult.

I harvested exclusively from microbatch under oil for a little over half a year due to a crystal form that grew in 20%+ volatile alcohol (hanging drop tended to swirl about something fierce when unsealed). I found that the main problem is getting the crystal up through the oil, as paraffin oil tended to knock crystals out of loops when pulling out of the aqueous layer. Al's oil is a little easier, but still not a cake walk. However, residual oil on the surface of the drop/loop didn't significantly affect diffraction. It was a little harder to see the crystals in the loop with blobs of oil getting in the way, but not impossible

----

A few schemes that worked well for me:

1. Step-wise supplement the drop with small volumes of mother liquor + over-concentrated cryo. For example, if starting with a 2ul drop, add 0.5ul at a time of mother liquor + 30-40% glycerol. Once you've done this 4-6 times, you'll have (relatively) gently moved into 20% glycerol while staying under oil. Different crystal forms may demand different steps/concentrations of the cryo stock.

or...

2. Use a pipete to remove all but a thin layer of oil from the top of the drop and then increase the drop volume to 4-6ul with mother liquor. This leaves a thin film of oil to slow down evaporation, but isn't quite so hard to pull crystals through. If you aren't in a volatile condition, you could just remove all of the oil by flooding the drop this way . Then transfer to a separate well with cryo (also covered with a slick of oil, if the condition is volatile).

3. As for crystal/loop handling, the hanging drop method of setting the loop parallel to the surface of the drop and then pulling up is awful for microbatch, as this causes the oil to shove the crystal out of the loop almost every time. I found that 45 degrees to nearly perpendicular to the surface of the drop tended to work best.

A nice way to use cryo is to add it under the oil into the drop let it sit for the time you need and just fish it with the oil then the crystals will be already protected. It worked for me and others in the lab and it also enlarge the volume of the drop so you can easily fish.

I don't typically use the oil as a cryoprotectant.

First I remove *most* of the oil from the plate, and then remove the bulk of the oil from the well where I'll be working. Next, I use a piece of clay to hold the plate at an angle, which makes it easier to get at the well. Then, I either

(a) fish the crystal directly from the well (through the remaining oil) and transfer it to a small drop of cryoprotectant on a cover slip; or

(b) I use a pipet to transfer the drop to a cover slip and then work from there (in the latter case, you'll bring some oil along, which will coat the drop after you deposit it on the cover slip, which helps prevent evaporation and allows you to perform the subsequent steps at a leisurely rate).

Handling Crystals continued...

Microbatch Crystal Mounting Tips...continued

We pour off the oil and then add a harvest solution (~10-20 ul to each terasaki plate well) with ~2% more PEG than that in the droplet (remember that the drop concentrates with time - sometimes fine tuning of the harvest solution PEG concentration is required but generally 2% works.). This keeps the crystals stable and displaces any oil remaining at the top of the droplet. Sometimes there is a skin on top of the droplet. This is removed by a capillary or acupuncture needle. Then we remove the crystals as per sitting drop. We have tried to cryo-protect the crystals by just pulling them up through the oil but this has not worked for our crystals. It may be possible to add a cryoprotectant to the harvest solution but we haven't tried it.

Comments

1. Most people simply leave the oil, and loop the crystal out through the oil.

2. The crystal must fit the loop well, or the surface tension will drag it off the loop.

3. People who are used to working with oil claim it is easier than sitting or hanging drop because the oil prevents evaporation. Therefore you don't have to work fast.

4. A loop with a bent handle can be helpful, because you have to harvest crystals from above.

5. Tip from Jeroen Mesters: if you want to use the oil as a cryoprotectant, you must DRY the oil first. Use ordinary paraffin oil, and put 1 ml aliquots into Epi-tubes. Dry tubes e.g. in a SpeedVac overnight. Freeze tubes, and use for a day, then discard. To use as a cryoprotectant, place a drop of dry oil on a glass slide. Drag the loop with the crystal through the oil along the surface of the glass. Small drops of mother liquor will stick to the slide. Remove as much mother liquor from around the crystal as possible, and freeze in the normal way. (Have I got that right Jeroen?)

I've mounted many crystals from microbatch and sitting drop plates and haven't found it difficult to mount xtals from either! (well, of course a bit difficult when I first started mounting xtals!!)

Typically I try to remove the oil by dragging the xtals gently in the cryoprotectant drop until I see the oil layer is removed (at much as I can judge visually!). It's a tricky job removing the oil completely, depending on the cryo (eg. paratone!!!!) so great attention is needed in doing this part! I transfer the xtals to a fresh drop of cryo before mounting.

----

1. Try to change to hanging drop vapor diffusion, by halving the precipitant.
2. Flood the microbatch drop with the first stabilizing/cryosolution, then remove the oil layer.

We usually dip the loop straight through the oil drop and try to 'fish' out the crystal. We then transfer it to a fresh drop of cryosolution and scoop it back out before mounting it in into the beam. This however isn't as easy as it sounds and takes a little practice. We do sometimes remove the oil drop (partially) to make it a little easier. Furthermore, if we use oil as a cryoprotectant, we would transfer it to a paratone (not paraffin oil) drop before mounting the crystal.
I have never heard anything about using the paraffin oil on top of the drop as a cryoprotectant. However, I found out that using paratone as a cryoprotectant is also very difficult, and as for all the described techniques, practice makes perfect.

Crystal and Age

How Does the Age of a Crystal Affect X-Ray Diffraction Data?

Reading and References:
The crystal structure of yeast phenylalanine tRNA at 2.0 Å resolution: cleavage by Mg2+ in 15-year old crystals. Luca Jovinea,, Snezana Djordjevica and Daniela Rhodes. Journal of Molecular Biology, Volume 301, Issue 2, 11 August 2000, Pages 401-414.

Abstract: We have re-determined the crystal structure of yeast tRNAPhe to 2.0 Å resolution using 15 year old crystals. The accuracy of the new structure, due both to higher resolution data and formerly unavailable refinement methods, consolidates the previous structural information, but also reveals novel details. In particular, the water structure around the tightly bound Mg2+ is now clearly resolved, and hence provides more accurate information on the geometry of the magnesium-binding sites and the role of water molecules in coordinating the metal ions to the tRNA. We have assigned a total of ten magnesium ions and identified a partly conserved geometry for high-affinity Mg2+ binding. In the electron density map there is also clear density for a spermine molecule binding in the major groove of the T?C arm and also contacting a symmetry-related tRNA molecule. Interestingly, we have also found that two specific regions of the tRNA in the crystals are partially cleaved. The sites of hydrolysis are within the D and anticodon loops in the vicinity of Mg2+.

Atomic resolution structure of a succinimide intermediate in E.coli CheY. Simonovic M, Volz K. J Mol Biol. 2002 Sep 27;322(4):663-7.

Abstract: Isomerization of aspartate to isoaspartate occurs spontaneously in proteins, causes changes in protein structures, and correlates positively with the aging processes of many organisms, including Alzheimer disease in humans. Aspartate isomerization proceeds through an unstable cyclic succinimide intermediate. There are few protein structure determinations that have characterized the intermediates and products of this isomerization reaction. Here we report the discovery of an unusually stabilized succinimide ring in the 1.1A structure of the Escherichia coli CheY protein, as determined from a crystal eight years old. The ring is formed by the side-chain of aspartate 75 and the backbone nitrogen of glycine 76 in an exposed loop of the molecule. Stabilization of the succinimide is through interaction of a sulfate ion oxygen atom with the imide nitrogen atom. Formation of the ring caused conformational changes in the loop, but did not alter the overall structure of the protein.

Using rational screening and electron microscopy to optimize the crystallization of succinate:ubiquinone oxidoreductase from Escherichia coli. R. Horsefield, V. Yankovskaya, S. Törnroth, C. Luna-Chavez, E. Stambouli, J. Barber, B. Byrne, G. Cecchini and S. Iwata. Acta Crystallographica Section D, Biological Crystallography Volume 59, Part 3 (March 2003).

Synopsis: Crystals of SQR that diffract to 2.6 Å were obtained by rational screening and sample quality analysis using electron microscopy.
From the publication: "It proved critical to freeze the crystals within 72 h of crystallization set-up. Crystals that were frozen after this time limit showed no diffraction. This alteration in properties was apparent by the change in colour from deep orange to pale yellow that was observed in crystals more than four weeks old (Fig. 1c). The deep orange colour of the crystals is attributed to the presence of haem b within the protein. The loss or breakdown of haem, demonstrated by the change of colour in the crystals, could lead to structural instability and consequently loss of diffraction. "

CryoLoops for X-Ray Data Collection at Room Temperature

We use a much easier test for mounting crystals at room temperature. Just coat the crystal with Paratone-N (HR2-643) and mount your crystal in a standard CryoLoop. The Paratone-N will slow down evaporation enough - no special tools required. You don't even need to remove all the liquid as you would do for flash-cooling the crystal in Paratone-N. A major advantage is that you can use the same crystal to collect under cryo conditions and directly compare the impact of cooling the crystal.

Reference: CCP4 Bulletin Board January 16, 2009 from Filip Van Petegem, The University of British Columbia.

Methods, Procedures, Technical

Using Stock Solutions from the Refrigerator

When using stock solutions from the refrigerator or any one that has been standing for some time, be sure to thoroughly mix it before use. Storing stock solutions in the refrigerator can result in condensation forming on the inside upper portion of the bottle. If this condensation falls into the stock solution, it will create a heterogeneous stock concentration which in turn could make reproducing the experiment difficult. Condensation can occur with any seal when there is a temperature change in the environment. So it is possible for this phenomena to occur with room temperature stored stocks if the temperature in the room changes significantly. To avoid such problems, it is generally good technique to mix crystallization reagents prior to pipetting.

Want Control and Accuracy?

Use a gel-loading pipet tip to dispense small drops with better control and accuracy of drop placement.

Mixing Drops

If you routinely mix the sample with the precipitant by aspirating and dispensing the drop several times, try setting up the drop without mixing. Simply pipet the precipitant into the sample and let the two diffuse together without mixing. On the other hand, if you usually set up your drop without mixing, try mixing. During the 2005 RAMC meeting, a show of hands survey among 100 participants showed most people do not mix their drops.

Make Connections

Communicate. Call (no e-mail allowed) a colleague and ask them their favorite crystallization trick or tip. Offer up one or two of yours.

PEG 400 and MPD

If you are using PEG 400 as a precipitant with some success, try MPD. If you are using MPD, try PEG 400.

Read the Classics

Read the classics. Try Laboratory Experiments in Biological Chemistry by James B. Sumner and G. Fred Somers, Academic Press 1949.

Trying Different Precipitants

Escape the local minima of using the same precipitants. If something worked once, great. Try it again, but remember to try something new.

Check Out Temperature

Try different temperatures. Room temperature and 4°C are the norm and work quite fine. Anything between 0°C and 37°C is fair game. If you do not have an incubator, simply look for a cool or warm space in the building to incubate the plates.

Free Interface Diffusion

Try free interface diffusion as a crystallization technique. This is easy to do and requires only a small amount of sample. Using a 20 µl microcapillary pipet, pipet 2 to 5 µl of sample into one end of the capillary. Next, carefully pipet 2 to 5 µl of precipitant SLOWLY into the capillary without introducing an air bubble. Seal the ends with wax or clay. It helps to pipet the less dense material onto the material of higher density (i.e. pipet sample onto 30% PEG 8,000, pipet 15% Isopropanol onto the sample). Use gel-loading pipet tips to load the sample and precipitant.

Removing Mother Liquor

Tired of cutting filter paper for wicks to remove mother liquor from capillaries during crystal mounting? Try our Paper Wicks™. The 55 mm X Fine Long (HR4-211) work great in 0.75 mm capillaries.

Methods, Procedures, Technical continued...

PEG Sensitivity

Keep stocks and working solutions of PEGs in the dark. Use amber or solid colored bottles or wrap clear bottles in foil. If you want to be really careful, purge with Argon and freeze them.

About Growth Rate

As a general rule, larger and finer crystals are obtained if the growth rate is minimized. If you are growing microcrystals, reducing their growth rate by more gradual equilibration with the reservoir may result in their attaining larger size.

Reducing Agents

Consider using a reducing agent as a variable in the crystallization. Include a small amount (0.001 to 0.01 M) of a mild reductant such as TCEP hydrochloride, Cysteine, B-Mercaptoethanol, Glutathione, or Dithiothreitol in the mother liquor. Besides protecting sensitive Cysteine residues, there is some indication that antioxidants play some other undefined role in crystallization. Try levels of reducing agent much higher than that generally thought necessary to maintain sulfhydryl function.

Do Not Disturb

Once crystallization conditions are relatively well established, set up a crystallization trial and do not examine or disturb it in any way for several weeks. Premature handling of crystallization trials can convert a few promising growth centers into a massive shower of microcrystals.

Using Sodium Azide

Keep crystallization samples and hardware free from microbial presence by filtering all solutions through a 0.22 micron filter. Store stocks and working solutions in sterile containers. In most cases this negates the need for antimicrobials such as Sodium azide.

Bioseparation

Consider crystallization as a tool for bioseparation.

Temperature Effects

Proteins in high salt are usually more soluble at lower temperatures than higher temperatures. The reverse is generally true for PEG and MPD. Keep this in mind during initial screening and optimization. Also keep in mind that this is not always true.

pH pHun

pH adjustments in the drop can be made by adding a small amount of concentrated Ammonium hydroxide to the drop or reservoir to increase the pH, or Acetic acid to lower the pH.

Cold Organics

If you are using organic solvents as precipitating agents, be sure to include 4°C incubations with your trials.

How to Dilute

A 1:10 dilution can be defined as 1 part of stock plus 9 parts of diluent. For example, to make 1,000 µl of 0.1 M buffer from 1.0 M buffer, simply pipet 100 µl of 1.0 M buffer into a tube and add 900 µl of diluent (water).

Methods, Procedures, Technical continued...

What is Your Definition of % W/V?

Percent Weight/Volume (% w/v) = the weight in grams of a solute per 100 milliliter of a solution. For example, a 50% w/v solution of PEG 6,000 is made by adding exactly 50 g of PEG 6,000 solid to a total, final volume of 100 ml. NOT by adding 50 g of PEG 6,000 to 100 ml of water.

Removing Urea and Acrylamide

Urea and Acrylamide contamination of RNA samples from denaturing gels cannot be removed by dialysis. Acrylamide and Urea can be removed using a strong cation exchange resin. Joe Ng, UAB.

Path and Endpoint

The path is as important as the endpoint. Vary the method, drop ratios, and reservoir volume to alter the path to the same endpoint as a variable during optimization.

Inorganic False Positives

Beware of inorganic salt crystals when using Phosphate, Carbonate, or Borate buffers!

Condensation

Tired of condensation problems in the plates at 4°C? Fill two dummy plates with water, seal and place one at the top and the other at the bottom of your stack of plates. Voila! No condensation problem!

Taking Care of PEGs

Polyethylene glycols are inherently unstable and are prone to produce aldehydes and peroxides. The presence of these oxidation byproducts increase with the age of the PEG and is promoted in the presence of UV light. One can slow the production of aldehydes and peroxides by storing the PEG at low temperatures and in the absence of light and oxygen. Flooding the storage bottles with Argon will help limit the oxidative effects of oxygen on the PEG. An increase in the oxidative byproducts will inherently change the pH, conductivity, and ionic strength of the PEG.

Sodium Azide and Heavy Metals

Never use Sodium azide in crystallization reagents that contain heavy metals since the combination poses the danger of forming explosive metal azide salts (See Problems associated with the use of azide as an inhibitor of microbial activity in soil, M. Rozycki and R. Bartha, 1981, Appl. Env. Microbiol. 41: 833-836).

Equilibration Kinetics

Recently we chatted about ways to alter the equilibration kinetics in a hanging or sitting drop vapor diffusion experiment. Another way to fool with the kinetics is to perform the experiment at a cool temperature. Mikol et al have described how both the protein and precipitant are concentrated three to five time faster at 20°C than at 3°C. For details see V. Mikol, J.L. Rodeau, R. Giege, 1990, Anal. Biochem. 186, 332-339, Experimental determination of water equilibration rates in the hanging drop method of protein crystallization.

Physical Chemical Aspects

Always take into consideration the effect that salts, polymers, organic solvents, and additives might have on the pH of the buffer selected for the crystallization experiment. To be safe, check the pH of an experimental solution after all of the reagent components have been added, mixed, and the solution has equilibrated to the temperature where the buffer was titrated and the experiment is to be performed.

Methods, Procedures, Technical continued...

Using Different Reservoir Volumes

Although one typically uses 1,000 µl of reservoir solution in a VDX™ or Linbro® Plate, one can actually get away with 500 µl of reservoir solution before having to begin worrying about the excessive effects of evaporation which occurs when using polystyrene crystallization plates. The utilization of less volume in the reservoir can alter the kinetics of equilibration between the reservoir and the drop. Less volume equates to slower (longer) equilibration times. This is not necessarily a bad thing when screening for preliminary crystallization conditions. For a good read on the kinetics of macromolecular crystallization see "Kinetic Aspects of Macromolecular Crystallization" by Joe Luft and George DeTitta, page 110-130, Methods in Enzymology, Vol. 276, Part A, 1997.

Crystal Annealing

Flash-cooling crystals can sometimes increase the mosaicity of biological macromolecular crystals. In some case, macromolecular crystal annealing can reduce the mosaicity of flash-cooled crystals without affecting molecular structure. Crystal annealing involves cycling a flash-cooled crystal to room temperature and then back to cryogenic temperature. The procedure can also be applied to sometimes restore diffraction from flash-cooled crystals that were not properly handled to and from cryogenic storage. Crystal annealing does not seem to improve a poorly diffracting crystal suffering from molecular disorder. The essential features of the crystal annealing procedure are the following. The crystal is first flash-cooled. The crystal is removed from the cryostream and quickly transferred to a drop of cryoprotectant at crystal growth temperature and allowed to remain in the drop for at least three minutes. The drop should be covered to prevent evaporation. Finally, the crystal is remounted on a loop and flash-cooled. Reference: Macromolecular Crystal Annealing: Overcoming Increase Mosaicity Associated with Cryocrystallography, J.M. Harp, D.E. Timm, and G.J. Bunick, Acta Cryst. (1998) D54 622-628.

Isoelectric Homogeneity

Protein preparations which exhibit microheterogeneity are sometimes not amenable to crystallization or yield poorly diffracting crystals. Isoelectric heterogeneity is one such biochemical crystallization variable. Protein isoforms are often the result of modifications such a phosphorylation, methionine oxidation, or glycosylation. Such modifications can cause very small changes in the isoelectric point (pI) of proteins. These isoforms can sometimes be resolved by chromatographic techniques such as ion exchange (Crystallization of Isoelectrically Homogeneous Cholera Toxin, Westbrook & Spangler, Biochemistry 1989, 28 1333-1340). Conventional preparative isoelectric focusing techniques utilizing carrier ampholytes can often resolve isoforms, but suffer from pH gradient instabilities and residual contamination of the proteins by ampholytes. An alternative technique that can avoid these complications, PrIME (Hoefer Pharmacia Biotech) has been used successfully to further purify proteins which have subsequently been crystallized (Fab fragment of anti HIV gp-41 monoclonal antibody and isoforms of epidermal growth factor - Righettia et al).

Stabilizing Crystals with Glutaraldehyde

Soak crystals overnight in a solution comprised of the mother liquor utilized to grow the crystals plus 0.5 to 2% v/v Glutaraldehyde. Glutaraldehyde cross-links proteins through the epsilon amino group of lysines. Cross-linking can be used to stabilize fragile crystals for seeding or data collection.
Reference: F.A Quiocho and F.M. Richards. Proc. Natl. Acad. Sci. U.S.A. 52, 833 (1964).

Building Blocks

During the growth of a high quality crystal, identical components are incorporated into a periodic lattice. Thus, sample homogeneity, the presence of uniform biological macromolecules, is typically essential for the growth of high quality crystals.

Homogeneity

If members of a homogeneous population alter their form, then the population is no longer homogeneous. Stability of a population is important in order to maintain homogeneity. One should take measures to preserve the stability of the sample and make it resistant to change, in order to prevent denaturation and aggregation.

Read the Tea Leaves

We set screens in anticipation of growing crystals. In reality, we are looking for ways to alter the solubility of the sample in order to grow a crystal. Therefore, review screens looking for more than crystals. Look for variables that alter the sample's solubility. The big hitters are sample concentration, reagent type and concentration, pH, and temperature.

Methods, Procedures, Technical continued...

Reverse Vapor Diffusion

Reverse vapor diffusion can sometimes be used to crystallize a protein in low ionic strength. This is an alternative method to dialysis that is less tedious to set up but also allows the protein concentration to become more dilute as the experiment proceeds, whereas dialysis can maintain a constant protein concentration. Begin with the concentrated protein in salt. The concentration of salt should be sufficient to maintain the solubility of the sample, perhaps 0.1 to 0.5 M salt. Set the sample for crystallization using the hanging or sitting drop vapor diffusion method. Pipet deionized water into the reagent reservoir. Pipet the high ionic strength protein sample onto the cover slide (hanging drop) or post (sitting drop). Do not add water to the sample. Using only deionized water in the reagent reservoir will allow water to diffuse from the reagent reservoir into the drop. As the drop size increases by vapor diffusion, the ionic strength in the drop will decrease. The protein concentration will also decrease, so it is a good idea to begin with a concentrated protein sample. It is also helpful to avoid having too much salt in the samples since this may cause the sample drop to absorb too much water and dilute the protein concentration. For cryoprotection, one can add Glycerol to the reagent reservoir and mix this with the sample drop.

Gentle Crystal Cross-Linking with Gutaraldehyde

To cross-link fragile crystals for a chance at improved handling, solution changes or cryo, try the following: If you have hanging drops, then transfer the cover slide to a Cryschem™ 24 well sitting drop plate or place a Micro-Bridge™ into the 24 well hanging drop plate. Pipette 2 to 5 µl of 25% Glutaraldehyde into the sitting drop post and pipette your crystallization reagent into the surrounding reservoir. Seal the experiment. Allow the Glutaraldehyde to vapor diffuse into the sample drop containing the crystal. Thirty minutes to six hours is generally sufficient. Glutaraldehyde relies primarily on lysine residues so the number of lysines as well as temperature can be two significant variables influencing cross-linking time. Note that amines will interfere with Glutaraldehyde so Ammonium sulfate or Tris buffer will have to be dialyzed or exchanged out and substituted before cross-linking is attempted.

Note: Glutaraldehyde is toxic and precaution was taken against exposure to the reagent by conducting the cross-linking reactions in a chemical fume hood.

Cryschem Plate - Circle Your Hits

Circle your drops with crystals or promising results. With a Cryschem plate sealed using tape, simply use a Sharpie® to circle the drops that look promising and those that have crystals. This makes it easy to spot these drops later during follow up. We suppose you could get fancy and use different colors to code the results, but a simple black Sharpie circle around a well is easy to spot, even through a stack of plates.

Seeding from Wild Type Crystals to Grow Mutant Crystals

If you are able to obtain crystals of the native or wild type protein and cannot get crystals of variants or mutants of the native protein, try streak seeding. Streak seed from the wild type crystals into drops containing the variant/mutant.

Glover et al. streak seeded from wild type crystals, either immediately or after a day of equilibration. The seeding stock solution was prepared by diluting a drop with small crystals 100-fold using the reservoir solution. Streak seeding was performed by dipping a hair into the seeding stock solution and rinsed twice in the reservoir. Crystals grew to 100-400 micron in 1 to 2 weeks.

Using Evaporation to Control Crystal Nucleation

Jovine (2000) used an evaporation method to control excessive nucleation and produce larger crystals.

A vapor diffusion experiment is set with the sample and reagent concentration where no crystals form when the drop and reservoir are in equilibration with one another. Nucleation is effected by opening each vapor diffusion experiment (remove cover slide, film or tape) for a precise amount of time. The amount of time used by Jovine was 100-120 seconds. The amount of time is empirically determined and will depend upon drop volume, reservoir volume, temperature, and reagent formulation. The opening increases the evaporation of water from the drop and creates a small and temporary increase in the relative supersaturation, hopefully enough to promote nucleation before the system returns to equilibrium when the experiment is sealed. If the drop remains clear, the procedure can be repeated until crystals start to appear. If too many crystals appear, reduce the amount of evaporation time.

Methods, Procedures, Technical continued...

Using Evaporation to Control Crystal Nucleation continued...

This method can also be applied to experiments which remain clear, as a way to effect a change in the drop's relative supersaturation, which could result in a crystal, precipitate or phase separation.

Alternative Reservoirs in Vapor Diffusion Experiments

Setting up vapor diffusion crystallization experiments against different reservoir solutions may have a profound effect on the outcome of crystallization experiments. It has been demonstrated that one way to increase crystallization space is to set the same conditions over different reservoirs (Newman 2005). So, rather than screen more reagents, one can screen the same reagent set over two or three different reservoirs (such as Sodium chloride, Ammonium sulfate and Polyethylene glycol 3,350), in addition to the crystallization reagent. Using the screen reagent in four sets of drops and then using the reagent in addition to three alternative reservoirs expands the crystallization space as the path of equilibration and endpoint is unique for each reservoir solution.

Recommended reservoir solutions
1.25 - 2.0 M Sodium chloride
1.0 - 1.5 M Ammonium sulfate
30-50% PEG 3,350
20% PEG 3,350, 0.2 M Sodium chloride

Replacement reservoir solutions (approximate)
0.5 M Lithium chloride = 35% PEG 4,000
1.5-2.0 M Lithium chloride = 2.5 M Ammonium sulfate

Sodium chloride should be expected to act as a simple desiccant. Ammonium sulfate can desiccate and affect the pH of the drop through the gaseous NH_3 which is in equilibrium with the NH_4^+ in solution. PEG 3,350 should desiccate, although with different kinetics compared to the salts (Luft & DeTitta 1995).

Alternative reservoir solutions have also been referred to as common dehydrants, a generic reservoir, and desiccants. The use of a single, simple, concentrated solution for the reservoir in vapor diffusion crystallization experiments has been happening for decades (Dunlop & Hazes, 2005; Hempel, 1968; Luft et al., 1994; McPherson, 1992).

To speed delivery of the reservoir for 48 and 96 well crystallization plates that are set up manually, the reservoir solution can be transferred to a Multichannel Pipetter Basin (HR3-269) and delivered to the plate using a multichannel pipette. For automated experiments, the reservoir solution can be transferred to a MASTERBLOCK® 96 Deep Well Plate (HR3-105) or a Multichannel Pipetter Basin (HR3-269).

Methods, Procedures, Technical continued...

Skin on Drop

Are you seeing skin form on the surface of your drops containing sample and reagent and wondering what to do?

Skins on the drop are considered bad. These skins are believed to be a layer of denatured protein. Skins can slow down the rate of vapor diffusion.

Pick away the skin before mounting your crystal. If the skin wraps around the crystal, it can affect the limit of diffraction.

To avoid skins, one can try crystallize under oil.[1] Either put a few µl of oil on top of the sitting drop, or use the microbatch under oil method.

Keep in mind that covering the sitting drop with oil will affect the rate of vapor diffusion equilibration. The following oils are ranked in order of the rate of equilibration allowed by the oil: Paraffin Oil (slowest rate), Als' Oil (medium rate), Silicon Oil (highest rate).

Vibration

Should one be concerned about vibration during crystallization?

1. "Many years ago at Imperial College we did a fairly systematic experiment on vibration using lysozyme (hanging drops in Linbro trays). We placed one tray in the basement on a very solid concrete base, one tray was placed in an incubator, frequently used and known to vibrate a little (with frequent door opening and closing), and the third tray was placed on a rather strongly vibrating metal plate hanging from a ceiling on a piece of wire. The vibrations were produced by a small motor with an acentric piece of metal attached to its rotor. The trays were examined at regular intervals. Crystals grew in all of them. The basement tray gave fewer but bigger crystals, but this may have been a small temperature effect - temperature was not controlled very well. Crystals from all trays were nice, they diffracted to the same resolution, with virtually identical Wilson distribution. After this experiment we stopped worrying about vibration." Tadeusz J. Skarzynski, 2006 CCP4 Bulletin Board

2. "...This is not to say, however, that absolute silence or stillness must prevail in the presence of growing crystals. At the Massachusetts Institute of Technology all the tRNA and protein crystals were grow in a cold room that had a giant compressor attached and contained, as well, several ancient centrifuges and shaker baths. One could observe standing waves in the reservoirs of all the vapor diffusion chambers and frequently could scarcely converse above the sound. Whether this had a positive or negative effect, we could not be sure. It is more likely that dramatic changes in the environment, as those caused by handling, are more disruptive than ambient conditions themselves." Alexander McPherson (1976) "The Growth and Preliminary Investigation..." in Methods of Biochemical Analysis, Vol. 23, page 284.

3. CCD Video Observation of Microgravity Crystallization of Lysozyme and Correlation with Accelerometer Data. E. H. Snell, T. J. Boggon, J. R. Helliwell, M. E. Moskowitz and A. NadarajahActa Cryst. (1997). D53, 747-755.
Synopsis: Stepped growth rates and crystal movements have been observed by CCD video in microgravity lysozyme protein crystallization experiments which correlate with `g-jitter' accelerations, especially of low frequencies. The spurts and lulls of crystal growth may, therefore, explain the residual mosaic block structure seen in protein crystal mosaicity and topography measurements.
Additional Comment by James Holton: They saw a very clear conneciton between vibrations and crystal growth rates and indeed crystal quality. Things like "astronaut exercising" coincided with increased crystal growth rate a short time later. So, it would appear that even in the most controlled environments vibration control can be a challenge, but at least on the Shuttle, where everything gets logged, you can (could) look for relationships.
And a comment from Eddie Snell: Basically, for vibration there are two factors, frequency and magnitude. Any high magnitude vibration is bad, i.e. the sudden short duration, hopefully low frequency one when you drop your tray :) For the same magnitude, low frequencies (a few Hz) are worse than higher. frequencies (mains frequency). High frequencies are quickly damped in a liquid environment. Measuring vibrations is fairly easy, translating that measurement into something useful is not. In the case James mentioned, we were looking at the reduced acceleration environment. Certain crystallization processes lasted over a longer time period than on the ground - in this case the presence of a halo of depleted solution around the crystal caused by the diffusion limited transport of the protein to the crystal face. Every time an astronaut exercised, this halo broke down and a growth spurt occurred (except for one astronaut who didn't exercise very hard at all, however he/she shall remain nameless). On the ground, this depletion zone is only there for a short period of time if at all. Transport and therefore growth is dominated by convection - the density differences cause flow of sample across the growing crystal face. Any effect from vibration at high frequency in a liquid medium would only be meaningful if the magnitude of that vibration was large. Diffusion processes and surface tension effects in the drop and Brownian motion and surface dynamics on the crystal face probably dominate the crystallization process at the macromolecule scale. Although I don't think vibration will be too big of an issue unless the magnitude is large I personally like small bench top Peltier controlled

Methods, Procedures, Technical continued...

Vibration continued...

forced air incubators. I can rule vibration out as a variable. Vibration isolation may make a difference with large magnitude vibrations, however vibration reduction would be cheaper. The best thing to do is try a simple experiment with a few of your favorite proteins. Set up a tray in one of the rooms if a colleague has one available and duplicate trays in other incubators set at the same temperature. If there is any big difference you have your answer (assuming it is not light, temperature control or a million other differences). Frequently I have often found that nice physical explanations in crystal growth are often poor approximations and later prove to be incorrect - a little shaking might be good after all. Perhaps that is why there are so many crystallography groups in California :)

His Tag and Ni Help Phasing

Structure of Mycobacterium tuberculosis mtFabD, a malonyl-CoA:acyl carrier protein transacylase (MCAT). Hemza Ghadbane, Alistair K.Brown, Laurent Kremer, Gurdyal S. Besraa and Klaus Futterera. Acta Cryst. (2007). F63, 831–835. The crystal structure of M. tuberculosis mtFabD, the mycobacterial MCAT, has been determined to 3.0 A ° resolution by multi-wavelength anomalous dispersion. Phasing was facilitated by Ni2+ ions bound to the 20-residue N-terminal affinity tag, which packed between the two independent copies of mtFabD.

Crystallization of (insoluble) Ligand Protein Complexes

Crystallizing ligands with limited or no water solubility can be tricky. Here are some suggestions.

A good review on the crystallization of protein ligand complexes can be found in Crystallization of protein–ligand complexes, Annie Hassel et al, Acta Cryst. (2007). D63, 72–79.

Solubilize the ligand in DMSO so it is maximally concentrated (100mM works fine). Add enough ligand to achieve two to three fold excess ligand to protein. Keep the DMSO concentration to no more than 3% to avoid damaging the protein. Set crystallization experiment using this sample. If you cannot achieve a high enough stock concentration of DMSO to be below the 3% threshold, dilute you protein in the storage buffer to approximately 1mg/ml. Add compound to two to three fold excess, incubate and co-concentrate to the desired concentration. This may help to avoid the DMSO shock. Alternatively one can incubate the concentrated protein with the compound solubilized in water for 24 to 48 hours and solubility of the ligand will be sufficient to complex with the protein. (Carsten Schubert ccp4bb December 2007)

One method that worked for me was to dissolve my ligand in 100% DMSO, as suggested in the previous response, then add a 3 molar excess of ligand to protein so that the final concentration of DMSO in the protein-ligand solution was no greater than 10% - of course the maximum concentration of DMSO that your protein can suffer will be protein specific but you could investigate this by incrementally adding DMSO to just a solution of your protein at your working crystallization concentration then measuring scattering at 600nm in a spectrophotometer to determine the critical DMSO concentration that causes your protein to precipitate (if you have sufficient protein to 'waste'!). If your ligand binds tightly to your protein at an equimolar concentration you can then remove excess ligand and DMSO by passing your sample through a G25 Sephadex column. (Rob Hussey ccp4bb December 2007)

If you grow crystals in polyethylene glycols or similar reagent you might try to solubilize the compound in a small amount of this reagent. This is helpful if you want just a 1:4 protein:ligand ratio. Sometimes solubility is low even in 5% DMSO (or diluted solutions of glycerol, alcohols and similar molecules). In these cases setting up drops in the presence a saturated solution and some precipitate of the compound may also lead to good co-crystals. As one molecule passes from the saturated solution to the “bound” state, a new molecule is solubilized from the precipitate, which gradually dissolves and passes from the solution to its binding site in the protein. Indeed, this sounds like a “soaking” experiment and it works well if the compound is colored, so that you can see if the crystals actually become of the same color. Just remember to wash them thoroughly before measurements, in order to remove traces of the ligand precipitate that would result in poor diffraction. (Marco Mazzorana ccp4bb December 2007)

We routinely obtain structures from protein solutions with a big pellet of ligand in the bottom of the tube. For co-crystallizations we add 1mM compound to a 0.3mM solution of the protein and incubate overnight. Many of the compounds are only soluble to 50 micromolar, so we get a lot of precipitate. The next day, we spin the tube at high speed, and use the supernatant for crystallization trials. We have started from 100 mM stocks in 100% DMSO or ethanol. This has worked for compounds ranging for picomolar to micromolar affinity, which surprised us, but it worked. (Kendall Nettles ccp4bb December 2007)

Methods, Procedures, Technical continued...

Glutaraldehyde to Differentiate Salt from Protein Crystals

Place the crystals in a low ionic strength buffered solution containing 0.2-.2.0% v/v Glutaraldehyde. Protein crystals will quickly be fixed (faster than they dissolve) into a light golden, gelatinous lump. Sometimes the crystals retain a crystal-like shape, other times the crystals leave just a rubbery blob. In contrast to protein crystals, salt crystals should dissolve over time and should not be colored.

One can add a small amount of 2% v/v Glutaraldehyde to the protein drop. Protein crystals in the presence of Glutaraldehyde will then turn a light golden color. Crystals fixed like this can then be put into a low ionic strength solution where salt crystals should dissolve. You can easily transfer Glutaraldehyde into a protein drop by vapor diffusion by adding it to the reservoir to make it 2-3% v/v.

A caveat to using this method is that there should be no free amines around other than on the protein (i.e., no Ethanolamine or Tris buffer, no Ammonium ions, etc.).

Note: Glutaraldehyde is toxic, causing severe eye, nose, throat and lung irritation, along with headaches, drowsiness and dizziness. It is quite volatile with a strong, obnoxious odor.

A suggestion from Michael Garavito, Michigan State University.

Making a Bigger Crystal or Changing Crystal Form

1. Screen additives. See Hampton Research Additive Screen™ and Detergent Screen™.
2. Use a crystallization screen as an additive screen. Make the reservoir 90% original reagent plus 10% crystallization screen reagent (Crystal Screen™, Index™, etc). Repeat using the entire screen.
3. Change the crystallization method: Sitting drop, hanging drop, microbatch, dialysis, free interface diffusion, etc.
4. Try limited proteolysis. Reference: In situ proteolysis for protein crystallization and structure determination. Nature Methods - 4, 1019 - 1021 (2007).
5. Add fresh protein to the drop once crystal growth has ceased.
6. Add water to the drop once crystal growth has ceased. Crystals may dissolve and grow larger or a new crystal may form.
7. Try the Silver Bullets™ screen from Hampton Research. Reference: Searching for silver bullets: An alternative strategy for crystallizing macromolecules. Alexander McPherson and Bob Cudney. Journal of Structural Biology 156 (2006) 387-406.

Optimization

Sialidase to the Rescue

Sialidase I from Clostridium perfringens (Glyko, Inc. Rosedale, NY, USA) was used by Ogawa et al (Acta Cryst. (2003). D59, 1831-1833) to remove terminal sialic acid residues and minimize the heterogeneity of the glycosyl structure on the protein and enhance crystallization. The protocol utilized 1 mU of Sialidase I in 50 microliters of 50 mM Tris-HCl buffer pH 6.8 at 310 K for 12 hours.

Substituting Sodium Malonate for Ammonium Sulfate

Xing and Xu (Acta Cryst. (2003) D59, 1816, 1818) recently describe the crystallization of the PX domain of cytokine independent survival kinase in Ammonium sulfate. Optimization of the crystallization seemingly involved the subtle manipulation of several crystallization variables, including using drop ratios (1:2 drop ratio), the removal of DTT to allow crystal growth after nucleation, as well as the substitution of Sodium malonate for Ammonium sulfate. The authors reported the Sodium malonate dramatically increased the reproducibility of the crystals and also acted as a good cryoprotectant. Crystals grown from 2.0 M Sodium malonate could be cryoprotected directly from the drop. The crystals grown in Sodium malonate were more resistant to physical shock compared to those grown in Ammonium sulfate.

Sample Purification as an Optimization Variable

If one is able to obtain crystals of a protein but the crystals do not diffract well, try further purification of the sample and repeat the crystallization conditions. Oftentimes crystals do not diffract well because of impurities or aggregates present in the sample. Impurities in the sample can cause dislocations and defects in the crystal, which can lead to poor diffraction. Further purification can sometimes remove these impurities and aggregates, resulting in crystals with improved diffraction. Oftentimes the reason crystals do not diffract can be traced to the molecules in the crystal not being well ordered in the lattice. Therefore, there is conformational flexibility or the molecules do not take a desirable or fixed conformation because the lattice forces are too weak. Or sometimes there are severe defects in the crystal lattice, which lead to disorientation.

Drop Size

Try increasing the drop size to grow larger crystals.

Remove Aggregates

Centrifuge the sample at 2,000 g for 10 to 15 minutes immediately prior to setup to remove aggregates and amorphous material.

Using Additives

During optimization of crystallization conditions, examine any additive that might for some reason tend to stabilize or engender conformity by specific interaction with the macromolecule.

Saving Kits

To reproduce crystallization conditions from a screen without taking additional solution from the screening kit (and making all your lab partners want to do evil things to you), simply set an additional drop or drops on the cover slide next to the original drop. One can set multiple drops on the same cover slide over the same reservoir. Pipet the sample onto the cover slide, then pipet the precipitant from the reservoir into the sample drop. Lastly, seal the cover slide over the reservoir.

Optimization continued...

Varying Ionic Strength

It has been suggested that lattice contacts within a crystal can be manipulated using ionic strength, which in turn can be used to influence crystal morphology. Rather than the type of salt used (Sodium chloride, Sodium acetate, Sodium citrate, etc.), one may manipulate the concentration of the salt or change crystal morphology. Typical salt concentrations to be screened for such manipulation are 0 to 500 mM.

Explore All Angles

Explore as many optimization opportunities for crystallization as possible. Optimize every hit from a screen. When you reach an optimization dead end for a particular hit, review the screens again and optimize crystal leads from other hits. Optimize different hits simultaneously if sample availability permits. This can save time if one hit leads to a dead end (poorly diffracting crystal, non-isomorphous derivative, etc.).

Beauty is Only Skin Deep

One's tendency is to optimize the largest, best looking crystals. Common sense. However, there are plenty of reports where small, miserable, ugly crystals have eventually produced the best data, so do not ignore the ugly ducklings.

Control

Control is a good thing. Having a handle on the variables which affect the crystallization and the ability to control these variables is key to the reproducible growth of high quality crystals.

Fresh Ligands

When working with ADP, ATP, NAD, NADH or other chemically unstable ligands as crystallization additives, be sure to use freshly prepared working solutions or properly stored stocks. These agents are sensitive to degradation over time which can influence the outcome of a crystallization experiment. Also, consider the pH of these ligands in solution since the pH of the additive agent can influence the final pH of the drop. It might be necessary to titrate the ligand solution before addition to the drop.

Increasing Crystal Size

How might one increase the size of a crystal which is grown from dialyzing the protein into pure deionized water? The following replies were posted on the cc04bb (http://www.ccp4.ac.uk) on October 21, 2005.

George Kontopidis: If I was you the first thing I will try is to increase protein concentration. Also after crystal formed you can take the solution to room temperature that also may help.With the existing crystals just open the container or the vial where the crystals formed to allow further evaporation (do not let it dry out) which will result to increase of protein concentration and hopefully increase crystal size.

A.ErtugrulCansizoglu: You might try vapor diffusion against water. As such you keep you protein sample in a mild-salty condition- where it doesn't actually crystallize, then set up your drops using pure water. This worked for a case in our lab. Slowing down the crystallization made the crystals bigger.

Sameer Velankar: I once crystallized a protein in similar conditions. For that matter many Thymidylate synthase crystallize by decreasing the salt concentration. You can add very little salt (15-25mM) in the drop and keep water or 2-5mM salt in the well. This controls the growth of the crystals and if you are lucky you will get bigger crystals.

Christopher F. Snook:I would suggest increasing the drop volume, i.e. going from say 4 to 8 microliters. This has a two-fold effect: an increase in the protein available for crystallisation and a reduction in the equilibration of the drop with the well solution. Another possiblity would be to increase the concentration which may increase the nucletaion at the expense of crystal growth.

deacona@mail.rockefeller.edu: I have never encontered such a situation, but maybe some microdialysis from your storage buffer against pure water may help somewhat? I believe this is a common strategy for antibody crystallization. As usual, micro/macro-seeding, varying protein concentration etc may also be of use. Just some thoughts...P.S. These may be of some interest J Biol Chem. 1970 May 25;245(10):2763-4 A crystallographic investigation of a human IgG immunoglobulin.Edmundson AB, Wood MK, Schiffer M, Hardman KD, Ainsworth CF, Ely KR.

Optimization continued...

Increasing Crystal Size...continued

J Mol Biol. 1997 Dec 19;274(5):748-56. Use of organic cosmotropic solutes to crystallize flexible proteins: application to T7 RNA polymerase and its complex with the inhibitor T7 lysozyme. Jeruzalmi D, Steitz TA.

Oleg Tsodikov: I would still spin down the crystals (or dissolve them in the presence of small amount of salt or glycerol in and some buffer) and then screen in a variety of different conditions.

David Aragao: We had, some years ago, a very similar case (salting inn?). Our crystals started to appear in the purification process everytime the ionic strenght decreased. The final crystals were big and we got 1.2 Å resolution from them. I know there are nice comercial dialysis buttons nowadays but we made our ones at the time. Maybe the description of our optimization process can help you (see materials and methods). Acta Crystallogr D Biol Crystallogr. 2003 Apr;59(Pt 4):644-53.

jjwarren@duke.edu: I would recommend that you check out Jeruzalmi, D. and Steitz, T.A. (1997) Use of organic cosmotropic solutes to crystallize flexible proteins: application to T7 RNA polymerase and its complex with the inhibitor T7 lysozyme. J. Mol. Biol., 274, 748-56. Their methods are generally applicable, but they focus heavily on proteins that crystallize at low ionic strength...

Christopher Colbert: Seriously, you might want to consider screening for additives.

Ewa Skrzypczak-Jankun: Try salt - increasing the ionic strength often makes crystals more bulky. Also adding salt will change saturation point and can slow crystallization If nothing else NaCl is CHEAP. Do you have any information about affinity to ions? what your protein likes and dislikes? digging in the literature can provide valuable clues.

Stephen Prince: You could try slowing the rate of cooling - there was an old recipe for insulin crystallization that involved slow cooling. One used a thermos flask containing water at above room temp, the protein mix was floated in this in a small test tube, the thermos was sealed and placed in a polystyrene box and left undisturbed for a week or so, crystals grew in the tubes as the solution cooled. You could try the same trick in a cold room ...

Jonathan Caruthers: I've seen the same effect on at least two occasions - actually I believe hemoglobin was first crystallized by dialyzing blood in water if memory serves. In any event, we managed to grow diffractable crystals simply by removing them from the fridge, partially melting them, and putting them back in the fridge to re-grow. This works pretty well.

William Scott: The main concern is stability. If you can find a more conventional crystallization, it might ultimately make your life easier.
The good thing is you know it will crystallize readily. (I assume this is a good thing to know, unless you are trying to do NMR)

Raji Edayathumangalam: If you want to pursue these very crystals - try oil, which retards nucleation and you get bigger (and often better) crystals. We've had a case before where crystals falling out of the protein solution weren't the best bet. They were inherently disordered - not the optimal crystals. Crystal screens yielded crystals in other conditions that diffracted to higher than 2Ang.

Jon Caruthers : actually, to follow up here, I grew crystals of a MBP-protein fusion construct using diet-coke as a buffer. It turned out that these crystals diffracted better than anything grown with any other buffer of similar pH (2Å vs. ~3.5Å with other buffers), so maybe there's something to this idea of using CO2 as a buffer.

Tassos Papageorgiou: Try dissolving the crystals in salt and dialyse them afterwards against water might help. Have you try to see whethre crystals grow in low ionic strength?

David Waterman: I had a similar case with a protein which crystallised on a drop in ionic strength. The protein was soluble in ~100 mM K Phos, and started forming crystals when this concentration was reduced by diluting with water (or glycerol, which had the bonus of being a cryoprotectant). The biggest crystals (blocks with sides up to 0.3-0.4 mm) were obtained after setting up a hanging drop of concentrated protein over a reservoir of water alone (no mixing!) and allowing this drop to grow slowly by vapour diffusion. These crystals were difficult to cryo-protect though, so a compromise including glycerol in the reservoir and mixing with the protein drop was found. It was certainly much easier than fiddling with dialysis buttons, though I might have been lucky.

Peter Moody: I crystallised a DNA repair protein by dialysis to remove the salt that kept it soluble. Crystal quality was much improved with 300mM sugar (Maltose seemed the best).

Optimization continued...

No Diffraction - What to Try?

a. The protein may have a high degree of structural flexibility and therefore structural heterogeneity. Try screening ligands, additives, co-factors and other small and large molecules that might help the protein assume a more rigid conformation.

b. Structural variations in the protein due to enzymatic modification, partial deamination, partial oxidation, other post translational modifications can lead to sample heterogeneity. Analyze your sample and conditions from expression to solubilization to purification to crystallization to identify what might lead to sample heterogeneity. Remove it or change it. If working with an enzyme, bind an inhibitor or ligand to the enzyme in an attempt to lock into a more rigid and homogeneous conformation. Reduce the number of steps and the amount of time between expression and crystallization.

c. If the crystal is growing overnight, the high rate of crystal growth may indicate a high level in the number of defects in the crystal lattice. Slow the rate of crystal growth. Reduce reagent concentration or protein concentration. Layer silicon oil over the reagent reservoir to slow vapor diffusion. Use less reagent in the reservoir. Evaluate drop dilution and drop ratios. For example, dilute the protein 1:1 with your sample buffer. Set vapor diffusion experiments with diluted sample:reagent drop ratios of 1:1, 2:1 and 3:1. The final protein concentration will remain similar between the original and diluted samples but the path of equilibration will be different and the rate will be lower than for the original drop.

d. Mount the crystal, pre cryo, in a capillary and test for diffraction to confirm that cryo is not causing the poor diffraction. If room temperature data is better than cryo, your cryo method and cryo procedure might benefit from further refinement.

e. Screen additives.

f. Screen crystallization kits as additives. Mix 70 to 85 µl of the optimized crystallization reagent with 30 to 15 µl of solutions from your favorite Hampton Research screen (Crystal Screen™, Crystal Screen 2™, Index™, SaltRx™, etc.) to create a 100 µl solution. Mix thoroughly. Pipet 100 µl of this solution into a 96 well sitting drop plate. Create a drop mixing equal amounts of reagent and sample, seal and allow to equilibrate. Varying the ratio of optimized reagent: screen reagent and drop ratio can also be tried. Watch out for false positive salt crystals as these random mixes may create insoluble salts. Look in the reservoir for salt precipitates or crystals. If one prefers to use 24 well plates, simply change the ratio of optimized crystallization reagent:screen reagent. For example, in a Cryschem™ Plate, try 350-450:150-50. In a VDX™ Plate, try 750-900:250:100.

Desiccating Crystals to Improve Diffraction

Desiccating, or drying a protein crystal can be a way to salvage or improve the diffraction quality. The procedure consists of removing a non-diffracting crystal from the X-ray beam, plunging it into a soaking solution made of the original crystallization reagent supplemented with a suitable cryoprotectant (glycerol, ethylene glycol, MPD, PEG 400, etc.) and then allowing the drop to dry in the evaporating sitting or hanging drop for 15 minutes to several hours. Try 1 ul cryo reagent plus 9 ul of original crystallization reagent for the drop. Remount the treated crystals and examine for diffraction. The procedure is originally described by Chantal Abergel. Reference: Spectacular improvement of X-ray diffraction through fast desiccation of protein crystals. Chantal Abergel. Acta Cryst. (2004). D60, 1413-1416.

Dissolve and Restore Protocol for Growing Larger Crystals

Impurities adsorbing onto the crystalline surface can prevent further growth of a crystal. Repair and growth of an impurity poisoned crystal is possible by using a dissolve and restore protocol described by Plomp et al (2003). By temporarily applying undersaturation conditions, an impurity adsorbed layer can be removed, which followed by saturation conditions can revive crystal growth with the potential for crystal growwth without the incorporation of impurities. Regular cycles of short periods of undersaturation followed by longer periods of supersaturation can be applied to dissolve and restore, with the potential of a larger crystal with fewer impurities and defects. Temperature manipulation (cycling) for samples with temeprature dependent solubility is a convenient approach. Altering and cycling sample and reagent concentration is another approach (Heinreichs et al (1992), Koeppe et al (1975), Przybylska (1989)).

Optimization continued...

Heavy Atoms and Salt Reagents

Heavy atom derivatives can sometimes be difficult to obtain in the presence of sulfate salt crystallization reagents such as ammonium sulfate or lithium sulfate.

However, difficult does not mean impossible, so be sure to screen heavy atoms in the salt based condition before trying to cure a problem that might not exist.

When one is unable to obtain succcessful derivatives in the presence of sulfate salt based crystallization reagents, one might try transferring the crystals to high concentrations of a similar acetate salt based crystallization. For example, Ammonium acetate instead of Ammonium sulfate, or Lithium acetate instead of Lithium sulfate. This will maintain the high ionic strength of the crystallization reagent yet increase the solubility of some heavy atoms. Acetate, in higher concentrations can also act as a cryo salt.

Try replacing the original salt with Sodium malonate or Tacsimate. Malonate: a versatile cryoprotectant and stabilizing solution for salt-grown macromolecular crystals. T. Holyoak, T. D. Fenn, M. A. Wilson, A. G. Moulin, D. Ringe and G. A. Petsko. Acta Cryst. (2003). D59, 2356-2358.

Try halide soaking using KI or KBr. Novel approach to phasing proteins: derivatization by short cryo-soaking with halides Z. Dauter, M. Dauter and K. R. Rajashankar Acta Cryst. (2000). D56, 232-237.

One might also consider trying 100 mM Cobalt hexammine or Iridium hexammine as derivatives in the presence of acetate salts.

Try cross-linking. A gentle vapor-diffusion technique for cross-linking of protein crystals for cryocrystallography. Carol J. Lusty. J. Appl. Cryst. (1999). 32, 106-112.

Sulfate Ions in the Active Site

Problem: Enzyme crystals grown in Ammonium sulfate having trouble binding ligand.

Solution: This is not an unusual situation with sulfate, and, yes, sulfate often occupies phosphate binding sites, particularly when you're work with 1-3 molar concentration of Ammonium sulfate. The simplest way to remove sulfate from the crystal is to transfer to high concentrations of citrate. From my own graduate work on GPDH in the 1970's, we just transferred the crystals from 3.0 M AS to 1.44 M Sodium citrate. While the crystals weren't stable in citrate for long periods of time (days), that is not an issue today with cryocrystallography and flash-freezing. You might even try formate or malonate, which can have a modest cyroprotectant behavior. Another, and perhaps more relevant, method is the one devised by Bill Ray in the late 1980's for phosphoglucomutase (PGM). Apo-PGM was crystallized in high AS, which caused the same problems as you are experiencing. Ever the perfectionist, Bill devised a systematic method to transfer PGM crystals from AS to a PEG solution that allowed the formation of enzyme complexes (Biochemistry 30, 6866, 1991). Bill also looked at glycine as a replacement as well. So there are a number of ways to "desalt" crystals without resorting to cross-linking, while preserving good diffraction characteristics. Michael Garavito, Michigan State University.

Vary the Method of Crystallization

Using the crystallization reagent that produced the initial hit, or reagent formulations which have been partially optimized, set additional crystallization experiments using other methods and techniques. If sitting drop vapor diffusion was used to produce the initial hit, try hanging drop, vapor diffusion, microbatch, free interface diffusion, or dialysis. Try different plates and different apparatus using the same method to discover whether the difference in equilibration will produce a better crystal, a crystal in a shorter period of time, or a different crystal form. The volume of the chamber or well, the space between the drop and the reagent, the shape of the chamber and the well, and also the method and time required to set the experiment may affect the outcome of the crystallization experiment.

The path is as important as the starting and ending points in determining ideal nucleation and growth conditions.

Optimization continued...

Omit the Irrelevant

If the crystallization reagent producing a hit is a complex mixture containing, for example, salt, detergent, additive, metal ions, ligands, reducing agent, EDTA, cryogen, or other chemicals, prepare optimization reagents based on the hit, but systematically omit each of the components, one at a time. Which chemicals appear to make a difference in the crystal size, number and quality? Omit from future optimization experiments any chemical which appears to be irrelevant. Identify and remove irrelevant chemicals before adding the evaluating new chemicals. As with the sample buffer, keep the crystallization reagent as simple as possible. Include only chemicals which promote and enhance sample stability, homogeneity and crystallization.

Optimization is an Art

The skill of crystal optimization is an art form that improves with effort, thought, discussion, reflection, reading, learning, trial and error, patience, tinkering and time.

The path of optimization is rarely linear and the variables affecting crystallization are not independent. This makes it impossible to sample all crystallization variables and evaluate them at fine intervals.

Optimization may follow a main trail, but there are typically many branches in the trail to consider, explore and evaluate. And typically, time and sample availability do not allow one to explore each and every branch.

So one is left with the question of what they should try or what they should do next to increase the size or improve the quality of of the crystal. And there are usually plenty of recommendations to consider. But which recommendations should be considered and tried and in what order or priority, and which ones should be ignored for now and tried later, or perhaps discarded altogether?

It is the art of an experienced crystal grower to consider the results of systematic experiments of many different samples over much time and use this knowledge base to synthesize the best plan for growing perfect crystals.

Optimization can be tedious and require numerous iterations before one uncovers which combination chemical and physical variables produce the perfect crystal.

Optimization is an art and a technical skill. As such, it is dynamic and improves in direct proportion to the number of challenges, the degree of the challenges, and experience.

A good crystal grower never is, they simply get better and better and better...

Build a Tool Box

A skilled craftsman knows they cannot do their job without the proper tools. Maybe some jobs can be accomplished with one or two common and simple tools, but a skilled craftsman, over time, will build not only experience, but also a tool box. A tool box of both general and specialized tools that will allow them to handle all tasks in an efficient manner. And over time, a skilled craftsman gains appreciation of the importance that quality, reliability and support bring when deciding which tools to acquire.

A crystal grower also needs to build a tool box. This tool box will consist of apparatus and devices, plates and seals, kits and reagents; some general, some specialized. Initially the crystal grower will want to acquire tools that have general utility. Later, more specialized tools can be added so that when the need arises, these tools will be available to use and evaluate. Access to a useful and broad portfolio of tools ensures the crystal grower will have the ability to evaluate those variables which could lead to the perfect crystal.

You can only use and evaluate what you have and know how to use.

Sample Preparation

Imidazole and Crystallization

Should one remove 1.0 M Imidazole from the sample after elution from a nickel column? In many cases it is good to have (an) additional purification step(s) following the elution of the sample from a Ni column. Size exclusion chromatography (SEC) is a convenient and effective way to remove the Imidazole. If one finds that Imidazole is an important variable in maintaining sample homogeneity, one can also simply reduce the concentration from 1.0 M to a more reasonable level (0.02 – 0.2 M) for inclusion of crystallization reagents. In some cases, a protein might not crystallize in the presence of Imidazole. To remove the Imidazole, one can try precipitating the protein in Ammonium sulfate and resuspending the sample in low salt buffer and purify by ion exchange or SEC. One can also remove Imidazole by dialysis. In one instance (personal communication from Artem G. Evdokimov) decent crystals could only be obtained using 0.6 M Imidazole/acetate buffer and two Imidazole molecules were seen occupying hydrophobic spots on the protein surface. Sometimes the reason Ni column purified proteins precipitate without Imidazole is that the Ni ions leak from the Ni column. The presence of Imidazole may have been chelating this excess and trace Ni and once removed, the remaining Ni may cause the protein with a His tag to aggregate in solution. One may be able to remove this excess Ni using a Ni chelating resin (Hampton Research catalog number HR2-312). Or one can leave the Imidazole buffer with the sample in a more reasonable concentration (0.02 – 0.1 M) or try Citrate buffer (chelator) or EDTA. If you are working with a metalloprotein and need metals in the sample, using the chelating resin rather than leaving a chelating reagent in the sample is obviously a better choice.

Heat Treatment

If a protein does not crystallize or gives poorly diffracting crystals, one might try heat treatment of the sample. This is a quick experiment with minimal equipment required. The procedure can reduce and/or eliminate protein that is not folded properly from the sample. Place the sample at 4°C for one hour. Incubate the sample at 37°C for one hour. Centrifuge the sample or filter using a 0.22 micron filter. Screen the heat treated sample for crystallization. The time course and temperature may require optimization for best results. One can monitor the heat treatment using dynamic light scattering or an activity assay. Tip from Annie Hassell, GSK – IUCr 2005.

Sample Too Soluble To Crystallize

The "solution" we hit upon for a problem protein with a high solubility profile was to cocrystallize it with an Fab fragment. Not the easiest route, but it worked. Catherine L. Lawson, Rutgers University. Reference: Li H, Lawson CL. (1995) Crystallization and preliminary X-ray analysis of Borrelia burgdorferi outer surface protein A (OspA) complexed with a murine monoclonal antibody Fab fragment. J Struct Biol. (115)335-337.

Dealing with Glycosylation

When having trouble removing glycosylation from a protein before crystallization, try a sequential exo-glycosidase(s) then endo-glycosidase treatment in order give the endoglycosidase better access. Or, try to prevent glycosylation in the first place and try glycosilation inhibitors (tunicamycine for example inhibits N-glycosilation). Another option is to try the expression of the protein in GnTI(i) HEK293S cells which are unable to synthesize complex N-glycans (Proc Natl Acad Sci U S A. 2002 Oct 15;99(21):13419-24. Reeves PJ, Callewaert N, Contreras R, Khorana HG. Structure and function in rhodopsin: high-level expression of rhodopsin with restricted and homogeneous N-glycosylation by a tetracycline-inducible N-acetylglucosaminyltransferase I-negative HEK293S stable mammalian cell line). One more alternative suggestion is to use your original expression system, but with Asn-Asp mutations of the glycosylation sites; assuming of course the mutant proteins will still be soluble which is straightforward to test. If the protein is resistant to treatment with Endo H or PNGase F under native conditions, try the Endo H treatment under only slightly denaturating conditions. Try screening a gradient of denaturating conditions to see if you can find a concentration that allows deglycosylation while not unfolding your protein.

There are reports where a fully glycosylated protein is able to be crystallized. So it may be worth a try to crystallize the glycosylated form. If the sample will still not crystallize, try deglycosylation, preventing glycosylation, or another cell line.

Sample Preparation continued...

Deglycosylation Summary

Deglyosylation Summary
(built on tips from the CCP4 community)

Glycoproteins are proteins to which a carbohydrate chain is covalently attached. Proteins modified in this way in many cases present a considerable challenge to X-ray structure analysis, because they do not easily form crystals. This is because the attached carbohydrate chains are often heterogeneous and flexible and interfere with the formation of crystal contacts. A well-known strategy to tackle this problem is to deglycosylate the glycoproteins prior to crystallization (see below for practical tips). This is usually done with endoglycosidases such as PNGase F (resulting in virtually complete removal of all N-linked glycans) or Endo H, Endo F1, F2, F3 (for partial deglycosylation). Also exoglycosidases can be used, alone or in combination with endoglycosidases. Alternatively, the glycosylation sites can be mutated (substitution of S/T to Ala or N to Gln or Asp in the conserved NXS/T motif). Expression in lower organisms like E. coli or Pichia pastoris is also an option, or - if a less radical procedure is required - genetically modified expression systems can be used that do not contain certain glycosyltransferases (e.g. CHO Lec cells).

Practical tips for enzymatic deglycosylation:

Several companies like Sigma-Aldrich and ProZyme have excellent theoretical and practical information about deglycosylation on their web pages, which are well worth studying. Both N- and O-glycosylation occur naturally in proteins, with N-glycosylation being the more common modification. N-glycans can generally be removed rather effectively by a single enzyme, PNGase F, whereas this is not the case for O-glycosylation, where several enzymes have to act in concert to exert the same effect. Deglycosylation can be tried both under native and denaturing conditions. While native conditions are in general preferable for crystallization purposes, deglycosylation under denaturing conditions is more effective and should for this reason always been done in parallel as a positive control. To achieve higher efficiency even under native conditions, one may experiment with using higher temperatures (up to 37°C, instead of 0-4°C) and/or longer reaction times (1-5 days; preferably adding some Sodium azide to the mixture to prevent bacterial growth).

In some cases, native deglycosylation does not work well. In these cases, one may try to deglycosylate the protein under denaturing conditions and then refold the protein. Alternatively, one may use only slightly denaturing conditions, by applying various mild detergents (like β-octyl-glucoside, Chaps, Triton X-100, SDS, etc.). One can also try to incubate the reaction mixture in a sonicating water bath. Yet another option is to deglycosylate the protein only partially using exoglycosidases (neuraminidase, galactosidase, etc.) instead of endoglycosidases.

In practice, one often starts out with a protein solution (concentrated to 0.5 to 5 mg/ml in water or a suitable buffer) and adds the glycosidase of choice (e.g. PNGase F, Endo H, Endo F1, F2, F3, neuraminidase or enzyme kits) in ratios varying from ca. 1:15 to 1:2000 (w:w). The deglycosylation reaction is then monitored regularly by taking samples and analyzing them on SDS-PAGE or IEF gels. A final check is preferably done by mass spectrometry. With some of the glycosidases like neuraminidase, one should be very careful to fully remove the enzyme (e.g. by gelfiltration), since it crystallizes easily even in minute concentrations. Another way to ensure complete removal is to use glycosidases as fusion proteins (coupled e.g. to glutathione-S-transferase; see Grueninger-Leitch, 1996) and passing the mixture through a GST affinity column (glutathione Sepharose) after the reaction is completed.

Of course, it is always well worth a try to also crystallize the protein in its fully glycosylated form. Some proteins even crystallize better in their glycosylated form, due to the involvement of the glycan chains in crystal contacts. Other proteins behave best when partially deglycosylated.

Glycobiology tools:

If one does get crystals from the glycosylated protein, one has to deal with handling carbohydrates, so here are a few practical tips: Modeling the ligand into the binding site, with or without supporting electron density, of course requires a 3D structural model of the carbohydrate ligand. This can be obtained either from scratch (e.g. using the modeling tool 'Sweet' from the www.glycosciences.de website, which converts carbohydrate sequences into 3D-models) or from a structure database (via the Uppsala HIC-Up server at http://xray.bmc.uu.se/hicup/ or directly from the PDB (http://www.pdb.org/) or other appropriate databases such as the Cambridge Structural Database (CSD; http://www.ccdc.cam.ac.uk/). The model of the carbohydrate ligand should then be refined and checked as carefully as the protein structure itself. Currently, however, tools for analyzing carbohydrate structures are not as widely known and applied as those for protein or DNA structures (see Kleywegt, 2003). A good tip is to check out the website at http://www.glycosciences.de. A couple of tools, such as pdb-care (to check carbohydrate residues in pdb files for errors) or carp (which generates Ramachandran-like plots for carbohydrates) or even GlyProt (to identify glycosylation sites in proteins and automatically attach them in silico) make life of structural glycobiologists significantly easier. Another database, currently under development, is EuroCarbDB (http://www.eurocarbdb.org/databases). Also, questions concerning carbohydrate nomenclature may be resolved by consulting the web site http://www.chem.qmul.ac.uk/iupac/2carb/.

Sample Preparation continued...

Compound Solubility with DMSO

Compounds produced in medicinal chemistry efforts often have low aqueous solubility when compared to biological ligands. When poor compound solubility is suspected, one may try Dimethylsulfoxide (DMSO) to solubilize the compound. Dissolve the compound in 100% DMSO and THEN dilute to a lower DMSO concentration. Dissolving a compound in dilute DMSO can be a very slow kinetic process.

Using L-Arg and L-Glu to Improve Solubility

Add 50 mM L-Arginine together with 50 mM L-Glutamic acid to the protein sample to improve protein solubility and long-term stability. Golovanov et al. reported a 3 to 8 fold improvement in solubilization with six different test proteins.

Reference:

1. A simple method for improving protein solubility and long-term stability. Alexander P. Golovanov, Guillaume Haubergue, Stuart A. Wilson, and Lu-Yun Lian. J. Am. Chem. SOc. 2004, 126, 8933-8939.

What Sample Concentration Should I Use for My First Crystallization Screen?

For most soluble proteins, 10 to 15 mg/ml in a sample buffer that promotes the sample stability, homogeneity and monodispersity will work fine for an initial crystallization screen.

A pre crystallization test such as the Hampton Research PCT™ (HR2-140) can be used to better determine the appropriate protein concentration for crystallization screening.

What to Use and What to Avoid in the Sample Buffer for Crystallization

Use the minimal number of chemicals and the minimal concentration of these chemicals necessary to promote sample stability, homogenity and monodispersity.

Use a buffer concentration between 10 -25 mM. This will allow crystallization reagents with a buffer concentration of 50 - 100 mM to manipulate the pH of the sample during the experiment.

Current trends seems to favor the use of 200 mM or less NaCl or KCl in the sample. Using no NaCl or KCl is just fine as well. It simply seems most overexpressed proteins are purified and prepared into a final sample buffer contain NaCl.

If the sample is known or expected to have free sulfhydyl residues on the surface, including a reducing agent such as TCEP hydrochloride can help to prevent oxidation of these residues. Oxidation of sulfhydryl residues can lead to sample aggregation. Avoid reducing agents if the sample has disulfide bonds in order to prevent cleaving.

If your screens contain di or poly valent cations such as Calcium, Zinc, Iron and others, avoid Phosphate, Borate and Carbonate buffers. Such mixtures can results in false positive salt crystals.

Phosphorylated Protein Samples

The crystallization of proteins with phosphorylation sites can often be difficult. It is imagined that such samples are susceptible to heterogeneity due to the presence of multiple species of protein in various states of phosphorylation. Careful sample purification and preparation is perhaps more of a significant crystallization variable than any particular crystallization trick or specialized screen. One can use a strong anion exchange chromatography with a shallow elution gradient to prepare a homogenous sample for crystallization. Isolation of a single phosphorylated form can produce crystals where as the presence of multiple phosphorylated forms can lead to precipitate, microcrystals or crystals less suitable for diffraction compared to those from a homogeneous sample. One may use mass spec to characterize the different elution samples following chromatography to assist in the selection of the best sample for crystallization.

Batch to Batch Sample Variation

Do not mix different batches of protein. Each batch of protein should be considered and treated separately. The reason being that the expression and purification conditions as well as the chemical and physical conditions are not identical for each batch. Even subtle differences between each batch can affect the outcome of a crystallization experiment. Each batch should be characterized and documented. Run at least an SDS-PAGE. If possible, consider also a native PAGE, IEF-PAGE, analytical gel filtration, mass spec and dynamic light scattering to characterize each batch. Save some protein from each batch for later experimentation, comparison, documentation, and reproducibility.

Screening

Co-Crystallize
Try crystallizing your sample with a substrate, coenzyme, inhibitor, or ligand. Sometimes these agents serve to fix the macromolecule in a more compact and stable form. This may impose a greater degree of structural homogeneity and increase the likelihood of crystallization.

Lose the Carboxy
If you cannot get diffraction quality crystals of your protein, try both Carboypeptidase-A and Carboxypeptidase-B to trim the carboxy terminus of the protein in order to generate smaller protein fragments which might be more amicable to crystallization.

High Quality Choppers
Use sequence grade Trypsin, Chymotrypsin, SV8 Protease and subtilisin along with inhibitors to generate small, active fragments for crystal screening. (Aled Edwards, McMaster University, CANADA & Brian McKeever, Merck, USA)

Seeing Double
Perform screens in duplicate at both 4°C and room temperature. If you notice a difference in solubility between the two temperatures, be sure to include temperature as a variable during optimization.

Screening Temperature with Limited Sample
Not enough sample to perform screens in duplicate at two different temperatures? Set up screens at room temperature. After four weeks move the plates to 4°C and watch for changes in solubility. Notice a difference? Use temperature as a variable during optimization.

Screening with Volatiles
Remember when using volatile organics as the precipitating agent that no reservoir needs to be added to the drop since distillation and equilibration proceed from the reservoir to the drop.

No Crystals?
No crystals, only precipitate in initial screens? Bring precipitant/protein concentration to just below supersaturation and vary pH and temperature to manipulate sample solubility.

Low Ionic Strength
Sample soluble at low ionic strength but forms a precipitate when dialyzed against water? This "salting in" effect can be used as a method to grow crystals. Begin with the sample in low ionic strength and dialyze the sample against a solution of lower ionic strength. Or, try changing the pH or temperature with the sample at a constant ionic strength. Charge distribution, surface features, or conformation may change as a function of these variables which in turn may influence sample solubility and the ability to crystallize the sample.

Sequence Homology Search
Uncertain about the ligand requirements for your sample? If you have the amino acid sequence for your protein, consider a sequence homology search to see if the sample is structurally related to other proteins with known ligand binding. Then try screening crystallization conditions including the ligands identified through the homology search.

Screening Continued...

Going from Nano Drops to Micro Drops

If you are having trouble reproducing crystallization initially found using nano drops (100 nl plus 100 nl for example) and are having trouble growing the crystals in the same conditions at µl volumes (1 ul plus 1 ul for example), one might consider the following tips.

Heather Ringrose (Pfizer UK) has suggested that if you initially screen with 100 nl (reservoir) + 200 nl (protein) you will pick up conditions that scale up to 1 + 1 µl.

Patrick Shaw-Stewart (Douglas Instruments, UK) reported that data-mining of published high-throughput results suggests that increasing the salt can help when scaling up from nanodrops. Presumably this speeds up equilibration. Patrick suggests that if you have a hit where the main precipitant is salt, try increasing the salt concentration in the reservoir solution by 1.0 M or more. Also, If you have a hit where the main precipitant is PEG or another organic, try increasing reservoir salt concentration by, say, 200 mM.

Using Old Screens and Reagents

Should one use an old crystallization screen kit that is past its "Best If Used By" date, or make screen and optimization reagents with old stock solutions?

The main issue would be the ability to reproduce any crystallization results achieved with the old reagents. With time, even at 4 and -20°C, the pH, ionic strength, concentration and stability of the reagents will change. Reagents containing Polyethylene glycol undergo oxidation which produces increased levels of aldehydes and peroxides which in turn lowers the pH and increases the ionic strength and produces small molecule species which can affect crystallization. Evaporation from the reagents, even when frozen, increases the concentration of solutes and decreases the concentrations of solvents. The result is that one might experience different results with an old reagent compared to a new reagent. An old reagent might not produce crystals as effectively as a new reagent. Or, the old reagent might produce crystals not able to be grown with the new reagent. In such cases it can be difficult or impossible to reproduce or optimize a crystal produced with an old reagent, using freshly prepared reagents. However, in these situations, some have reported success using the old reagent as an additive into freshly prepared reagents. For example, mix 1 part old reagent with 9 parts new reagent into the reagent well, mix and then add this reagent to the sample drop. This procedure will incorporate some level of pH, ionic strength and small molecule change from the old reagent into the new reagent.

The crystallization problems associated with old reagents versus new reagents seem sample-dependent. For some samples, a change in pH, ionic strength or the presence of a small molecule contaminant produced with age may have no affect on the crystallization. For some samples, the change might be advantageous and for still others, it might be other detrimental.

Biasing Crystallization Screen Reagents Towards Success

The following is a crystallization screening and optimization technique, which can be used in an attempt to improve the quality and size of a crystal or produce a different crystal form. First, one must begin with an initial crystallization reagent (ICR) which has produced some form of a crystal, microcrystalline precipitate or similar promising result. The ICR will be used to bias a subsequent crystallization screening experiment by adding the ICR to the crystallization drop, along with the sample and the screen reagent. Pipette the crystallization screen into the crystallization plate reservoir. One may choose to either repeat the original screen or choose a different set of screen reagents. When creating the drop, mix the protein, screen reagent and ICR in a 3:2:1 ratio. 3 parts sample : 2 parts screen reagent : 1 part ICR. The inclusion of the ICR in the drop modifies the crystallization screen, biasing the screen reagents with a promising reagent mix which may increase the likelihood for crystallization, improved crystals, or a different crystal form.

Possible modifications to this technique include: (1) varying the ratio of sample : screen reagent : ICR; and (2) modifying the bias such that one uses the ICR as the screen reagent and uses the original or new screen as the bias (3 parts protein : 2 parts ICR : 1 part screen reagent). This is essentially using the crystallization screen as an additive screen.

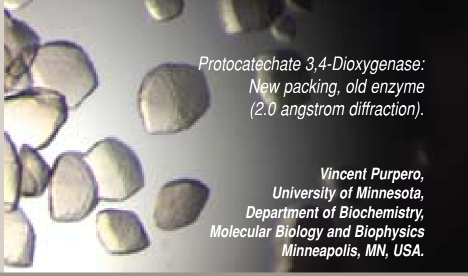
CRYSTALLIZATION BUFFERS TABLE

IN ORDER OF PH RANGES



Protocatechate 3,4-Dioxygenase:
New packing, old enzyme
(2.0 angstrom diffraction).

Vincent Purpero,
University of Minnesota,
Department of Biochemistry,
Molecular Biology and Biophysics
Minneapolis, MN, USA.

DESCRIPTION

Tabled below are buffers typically used in creating buffered crystallization reagents. Buffers should be used in the indicated ranges.

BUFFER	pH	
Potassium chloride	1.0	2.2
Citric acid pKa(25°C) (1) 3.13, (2) 4.76, (3) 6.4	2.2	6.5
Sodium citrate tribasic dihydrate pKa(25°C) (1) 3.1, (2) 4.8, (3) 5.4 Citric acid trisodium salt dihydrate	3.0	6.2
Sodium acetate trihydrate pKa(25°C) 4.8 Acetic acid sodium salt	3.6	5.6
Sodium cacodylate trihydrate pKa(25°C) 6.2 Cacodylic acid sodium salt trihydrate	5.0	7.4
MES monohydrate pKa(25°C) 6.15 2-(N-Morpholino)ethanesulfonic acid	5.2	7.1
ADA pKa(25°C) 6.6 N-(2-Acetamido)iminodiacetic acid	5.6	7.5
BIS-TRIS pKa(25°C) 6.5 2,2-Bis(hydroxymethyl)-2,2',2''-nitrilotriethanol	5.8	7.2
ACES pKa(25°C) 6.8 N-(2-Acetamido)-2-aminoethanesulfonic acid	6.1	7.5
PIPES pKa(25°C) 6.8 1,4-Piperazinediethanesulfonic acid	6.1	7.5
Imidazole pKa(25°C) 6.95 1,3-Diaza-2,4-cyclopentadiene, Glyoxaline	6.2	7.8
MOPSO pKa(25°C) 6.9 β-Hydroxy-4-morpholinepropanesulfonic acid	6.2	7.6
BIS-TRIS propane pKa(25°C) (1) 6.8, (2) 9.0 1,3-Bis[tris(Hydroxymethyl)methylamino]propane	6.3	9.5
BES pKa(25°C) 7.1 N,N-Bis(2-hydroxyethyl)-2-aminoethanesulfonic acid	6.4	7.8
MOPS pKa(25°C) 7.2 3-(N-Morpholino)propanesulfonic acid	6.5	7.9
HEPES sodium pKa(25°C) 7.5 4-(2-Hydroxyethyl)piperazine-1-ethanesulfonic acid sodium salt	6.6	8.5
HEPES pKa(25°C) 7.5 4-(2-hydroxyethyl)piperazine-1-ethanesulfonic acid	6.8	8.2

© 1991-2009 Hampton Research Corp. All rights reserved.

BUFFER	pH	
TES pKa(25°C) 7.5 N-[Tris(hydroxymethyl)methyl]-2-aminoethanesulfonic acid	6.8	8.2
MOBS pKa(25°C) 7.6 4-(N-Morpholino)butanesulfonic acid	6.9	8.3
DIPSO pKa(25°C) 7.6 3-(N,N-Bis[2-hydroxyethyl]amino)-2-hydroxypropanesulfonic acid	7.0	8.2
Tris pKa(25°C) 8.1 Tris(hydroxymethyl)aminomethane	7.0	9.0
TRIS hydrochloride pKa(25°C) 8.1 Tris(hydroxymethyl)aminomethane hydrochloride	7.0	9.0
TAPSO pKa(25°C) 7.6 2-Hydroxy-3-[tris(hydroxymethyl)methylamino]-1-propanesulfonic acid	7.0	8.2
HEPPSO pKa(25°C) 7.5 N-(Hydroxyethyl)piperazine-N'-2-hydroxypropanesulfonic acid	7.1	8.5
POPSO pKa(25°C) 7.8 Piperazine-N,N'-bis(2-hydroxypropanesulfonic acid)	7.2	8.5
EPPS pKa(25°C) 8.0 4-(2-Hydroxyethyl)-1-piperazinepropanesulfonic acid; HEPPS	7.3	8.7
TEA pKa(25°C) 7.8 Triethanolamine	7.3	8.3
BICINE pKa(25°C) 8.3 N,N-Bis(2-hydroxyethyl)glycine	7.4	9.3
Tricine pKa(25°C) 8.1 N-[Tris(hydroxymethyl)methyl]glycine	7.4	8.8
HEPBS pKa(25°C) 8.3 N-(2-Hydroxyethyl)piperazine-N'-(4-butanesulfonic acid)	7.6	9.0
TAPS pKa(25°C) 8.4 N-[Tris(hydroxymethyl)methyl]-3-aminopropanesulfonic acid	7.7	9.1
TABS pKa(25°C) 8.9 N-tris(Hydroxymethyl)methyl-4-aminobutanesulfonic acid	8.2	9.6
AMPSO sodium salt pKa(25°C) 9.0 3-([1,1-Dimethyl-2-hydroxyethyl]amino)-2-hydroxypropanesulfonic acid	8.3	9.7
CHES pKa(25°C) 9.3 2-(Cyclohexylamino)ethanesulfonic acid	8.6	10.0
Glycine pKa(25°C) 2.35 Aminoacetic acid, Aminoethanoic acid, Glycocoll	8.6	10.6
CAPSO pKa(25°C) 9.6 3-(Cyclohexylamino)-2-hydroxy-1-propanesulfonic acid	8.9	10.3
CAPS pKa(25°C) 10.4 3-(Cyclohexylamino)-1-propanesulfonic acid	9.7	11.1
CABS pKa(25°C) 10.7 4-(Cyclohexylamino)-1-butanesulfonic acid	10.0	11.4
Potassium chloride	12.0	13.0

SOLUBILITY TABLE

CRYSTALLIZATION REAGENT SOLUBILITY

DESCRIPTION

The following table provides data for formulating a saturated solution of the reagents listed at the temperature designated.

Reagent	Formula	MW	Temp (°C)	g/100 ml	[M]
Ammonium bromide	NH_4Br	97.95	15	53.8	5.5
Ammonium chloride	NH_4Cl	53.49	20	26.7	5.0
Ammonium citrate dibasic	$(NH_4)_2C_6H_6O_7$	226.19	25	56.54	2.5
Ammonium fluoride	NH_4F	37.04	20	37.0	10.0
Ammonium formate	$HCOONH_4$	63.06	20	63.0	10.0
Ammonium iodide	NH_4I	144.94	25	94.2	6.5
Ammonium nitrate	NH_4NO_3	80.04	25	90.2	11.2
Ammonium phosphate dibasic	$(NH_4)_2HPO_4$	132.06	25	46.2	3.5
Ammonium phosphate monobasic	$NH_4H_2PO_4$	115.03	25	28.7	2.5
Ammonium sulfate	$(NH_4)_2SO_4$	132.14	20	46.2	3.5
Ammonium tartrate dibasic	$(NH_4)_2C_4H_4O_6$	184.15	20	36.8	2.0
Barium nitrate	$Ba(NO_3)_2$	261.34	25	10.2	0.3
Cadmium bromide tetrahydrate	$CdBr_2 \cdot 4H_2O$	344.28	25	94.0	2.7
Cadmium chloride hemipentahydrate	$CdCl_2 \cdot 2.5H_2O$	228.35	25	97.2	4.2
Cadmium iodide	CdI_2	366.22	20	73.0	1.9
Cadmium sulfate hydrate	$3CdSO_4 \cdot 8H_2O$	769.52	25	70.3	0.9
Calcium chloride hexahydrate	$CaCl_2 \cdot 6H_2O$	219.08	25	67.8	3.0
Calcium sulfate dihydrate	$CaSO_4 \cdot 2H_2O$	172.17	25	0.208	0.01

GENERAL INFORMATION

ORDERS

By phone:

Telephone	(949) 425-1321
Toll Free in the USA	(800) 452-3899
Toll Free in Canada	(800) 452-3899

By Fax:

Fax	(949) 425-1611

By Mail:

Hampton Research Corp.
34 Journey
Aliso Viejo, CA 92656-3317 USA

By E-mail: info@hrmail.com

On the Internet: www.hamptonresearch.com

Telephone Orders

Hampton Research is available by telephone between 7:00 am and 5:00 pm Pacific Standard Time, Monday through Friday.

Fax Orders

Fax ordering is available 24 hours a day, 7 days a week. Fax orders are confirmed within 24 hours of receipt.

When placing an order please provide the following:

- Purchase order number
- Account name
- Shipping address
- Billing address
- Name of person to whose attention the order should be shipped
- Name and telephone number of contact person
- Product catalog number, description, size, and quantity

Order by Credit Card

Hampton Research accepts American Express, Visa and MasterCard orders via telephone, fax, and a secure internet shopping cart in USA dollar amounts only. Please provide credit card number, expiration date, card name, and billing address.

Standing Orders

Hampton Research can establish periodic shipments or large orders as standing orders. Please contact Customer Service.

Use of Products

Hampton Research products are for laboratory research use only and are not to be used for any other purpose including in vitro diagnostics, foods, drugs, medical devices, medical procedures, cosmetics, for/with/on humans, animals or plants, or for commercial purpose.

Pricing

Pricing is in USA dollars. Pricing is subject to change. Please contact Hampton Research or reference our website for current and correct pricing if you require this information before placing an order. Prices are confirmed at time of order.

Damaged Products

If you receive damaged products, notify Customer Service within 24 hours of receipt by telephone, fax, or e-mail to obtain instructions regarding claims.

Returns

Products may not be returned without prior authorization by Customer Service. A Return Authorization form must be completed and included with each return for proper handling. Please inspect packages upon receipt to be sure you ordered and received the items you need and expect. Notify Hampton Research of any discrepancies within 24 hours of receipt.

Shipping

All shipments are FOB Aliso Viejo, California USA. All orders received by 3:00 pm Pacific Standard Time will be shipped the same day unless the Shipping Department is out on a mountain bike ride. Orders requiring manufacture will be processed and shipping will be confirmed at the time of order. Shipping and handling charges are prepaid and added to the invoice.

Holidays

Hampton Research observes various USA holidays and random days off as well. Should your order arrive on a holiday, it will be processed and shipped the following work day.

Resale

Hampton Research products are not for resale except for distributors contracted by us.

Payment

Payment terms are net 30 days from shipment date. Payment is due in USA dollars. All bank drafts must be paid in USA dollars and drawn from a USA bank.

Suggestions and Comments

Hampton Research welcomes all suggestions, comments, and complaints pertaining to our products, service, and just about anything related to crystallization. Hampton Research is serious about delivering the best crystallization research tools and service to the crystallization research community. We appreciate you telling us what needs to be changed, improved, created or scrapped. Please direct ideas, comments and rantings to Bob Cudney. Telephone: (949) 425-1321 Extension 200. E-mail: bob@hrmail.com.

MSDS

Material Safety Data Sheets are available for products which are hazardous. Each Hampton Research product is intended for use by a qualified professional, trained in good laboratory practices and for those familiar with the potential hazards associated with laboratory research products.

Warranty and Liability

Hampton Research warrants that products conform to descriptions contained in the product specific literature and technical data sheets. Hampton Research is not liable for any claims or applications not listed in the Hampton Research literature. Hampton Research is not liable for the misuse of products, nor should information disclosed in the product literature be construed as a recommendation to use Hampton Research products in violation of any patents or applicable laws. Hampton Research's liability shall not exceed the purchase price of the product. Hampton Research shall have no liability for direct, indirect, consequential, or incidental damages arising from the use, results of use, or inability to use its products.

Technical Service

Technical Service is here to help with the most current and accurate information related to Hampton Research crystallization research tools and just about any topic related to protein crystallization. We welcome inquiries regarding biological macromolecular crystallization from product inquiries, screening and optimization strategies, or general brainstorming. We're here to help. There are numerous internet-based, technical resources at www.hamptonresearch.com or you can call, e-mail, or fax us. Telephone: (949) 425-1321 option 2. E-mail: tech@hrmail.com Fax: (949) 425-1611

CrystalNews E-mail Newsletter

Sign up for CrystalNews, an e-mail newsletter containing up-to-date information about biological macromolecular crystallization and crystallography. Tips, crystallographer related reading, meetings, community job opportunities, product announcements, and more. Send your e-mail to crystalnews@hrmail.com or visit www.hamptonresearch.com.

Thank You

Thank you for using Hampton Research crystallization research tools. Thank you to our customers, friends, families, fellow employees, and vendors who allow us to make a living doing what we enjoy (growing crystals). Best of success with your crystals!

Crystal Radio

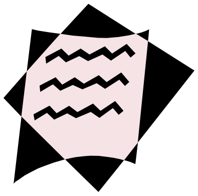
Abstract



Students learn the principles of radio waves by building a crystal radio.

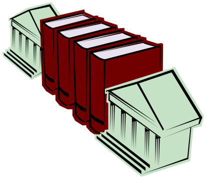
Equipment

1. Antenna
2. Copper Wire
3. Tank Circuit
4. Plastic Insulation
5. Detector
6. Germanium Semiconductor Crystal
7. Earphone
8. Piezoelectric Device

Grade Level

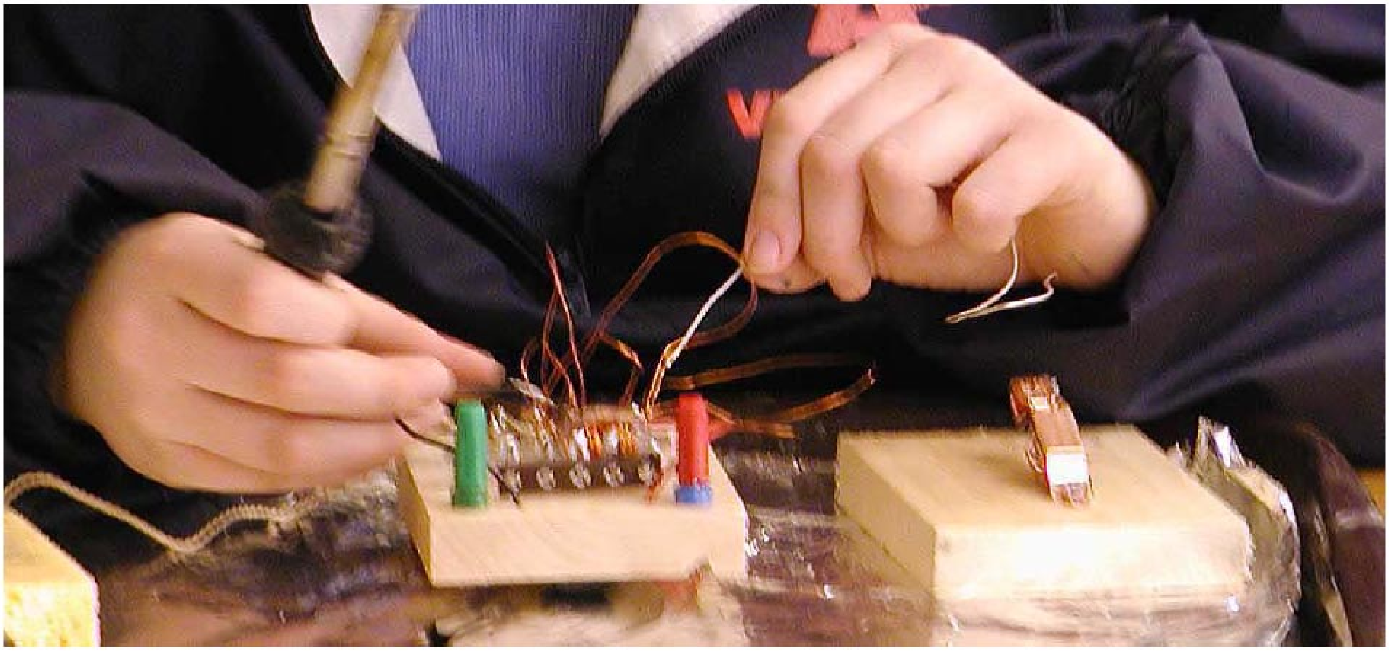
This activity is suitable for Elementary and Middle School Students.

State Standards Met



Standard 1 – Analysis, Inquiry, and Design
Standard 4 – Physical Setting and Living Environment

Build a Crystal Radio



This program is supported by:
the Cornell Center for Materials Research,
and
the National Science Foundation

Support for the Cornell Center for Materials Research is provided through the National Science Foundation as part of the Materials Research Science and Engineering Centers (MRSEC) program. Additional support is provided by Cornell University.

Make Your Own Crystal Radio!

Here at the Cornell University Center for Materials Research Radio Factory you'll make your own radio wave powered crystal radio set. You'll learn a lot about how your radio works and the special materials that you'll use to make it go. You'll also gain some valuable electronics construction skills such as the ability to recognize components and join them together by soldering.

How Your Radio Will Work

Here is a chart that shows how signals flow through the four different sections of the radio and are changed along the way.
In this chart we say a bit about what each section does, give its official radio builders name, and introduce a special material that is needed for the section to work

Here’s what the different sections in the radio do and the role the special materials play.

1) Catch Radio Waves:

The radio stations launch electric and magnetic forces through space that come and go a million times in a second. These electromagnetic vibrations are not always the same. In fact, the radio station changes their strength much more slowly, thousands of times per second to carry the messages in the form of words or music that they wish us to hear. You can send your voice a whole lot further by getting it to ride a radio wave than by simply yelling. For our radio wave catcher we can often use large pieces of metal that readily pass electricity. Things that pass electricity well are called conductors. We use electric forces in the radio waves to set electric current moving back and forth in time to the wave in the copper metal wires (more good conductors) that connect our radio at the antenna and ground connections. We need the material copper metal to bring these currents to the radio. Radio builders call the antenna the conductor that catches the wave in space. It can be the wire that comes with your set alone or a piece of metal such as an air duct. The ground is a connection to earth that allows the desired electric currents to pass from the antenna and through your radio. When running a home crystal set one can frequently use a cold water pipe, so long as it’s made out of a metal (often copper). The ``ground’’ doesn’t have to actually be connected to the earth. When we look for a good antenna and ground combination, what we are really seeking are two large conductors that are appropriately shaped and oriented (that means trying to see what works!) and are not already connected to each other. We can then hook up your radio between them (one side to the antenna connection, the other side to the ground connection) and catch the radio wave currents that pass back and forth between them. Please pay attention to avoid connecting your radio to power lines. I can’t warn you enough about how dangerous that is. There are lots more ideas about making good antenna and ground connections later in these notes.

To keep from losing our radio signal, we prevent wires we don’t want connected from touching with the colored plastic around them. Things that won’t allow electricity to pass through them, like the plastic, are called insulators. You’ll need many forms of insulators in your radio. See if you and your instructor can find some.

2) Pick out the Wave We Want:

Just as a swing swings best when we pump it at the right rate, the tank circuit composed of the coil and a capacitor will set an electric current sloshing back and forth if they are tuned for the right station, Around Ithaca, WTKO vibrates waves at 1,470,000 times a second and WHCU vibrates waves at 870,000 times a second. By adjusting the tank circuit to the right rate of electric vibration we not only select the station we want, but it is made stronger, just the reason we pump a swing at the right rate to make it swing well. To tune our tank circuit we change the size of the variable capacitor by adjusting the black tuning knob, just like in a regular radio. In the tank circuit the radio energy is swapped back and forth between the coil where it is stored as a magnetic field and the capacitor where it’s in the form on an electric field. The vibrations are managed in exactly this energy exchange process. The corresponding

Support for Cornell Center for Materials Research is provided through NSF Grant DMR-0079992

Copyright 2003 CCMR Educational Programs. All rights reserved.

process in a swing is to exchange energy of motion (greatest when you are swing through the low point) and energy in a gravity field (greatest when you are at the high points). When we want to store energy in a magnetic field, we use turns of metal wire to flow electricity in a loop. In the capacitor, we also use metal, but as plates that are close to each other, but not touching. We keep them from touching by using plastic insulation. That's a special material needed for the tank circuit. See if you can spot the metal/plastic sandwiches in the capacitor. Can you see what happened inside the capacitor when you turn the tuning knob?

3) Get the Message: To pull the message of music or speech off the vibrating current from the tank circuit is the neatest trick of all. This happens in the detector stage. This accomplished by our most special material: the germanium crystal diode. This is why our radio is called a crystal radio. Germanium, like so many materials that are at the heart of today's radio, TV's, electronics toys and computers, is a material that conducts electricity much more than an insulator, but not as well as a metal. Our crystal diode has a special property that is essential for pulling the message off the vibrating current: it passed current better one way than in the opposite direction. This allows the slow changes in the vibration that contains the electrical signals containing music or speech messages to be detected.

We can explain this in detail as follows: following the tuner stage, the radio uses a germanium diode to extract the audio signal from the much higher frequency radio wave that has carried it to this point. Since this signal is coded in the form of strength variations of the radio frequency wave, the detector acts in an analogous manner to the DC power supplies that have as their input the AC line voltage in a house. The principle it uses to extract the audio wave is to act as a one-way valve for electric current. Rather than confront the earphone of the last stage with an AC voltage that swings too fast by equal amounts toward positive and negative voltages (besides which, our ears would not detect such rapid variations anyway) the diode passes current in only one direction. Once smoothed by the earphone circuitry, this wave appears as immediately recognizable sounds. To repeat, the diode pulls the audio message off the radio wave that carried it great distances by passing its rapidly oscillating current in only one direction. The resultant signal is then smoothed in the last stage into a slowly varying wave. If we had admitted both directions of current flow, successive swings of the radio wave would have cancelled each other out during smoothing.

Can you think of other things at home that need to do tricky electrical transformations to do their job?

4) Make Sound: The last step is to turn the electric currents representing speech or music back into sound that we can here. Our earphone does this. It uses another special material that has the property of being piezoelectric: when we apply electricity to it, it changes its size a little bit. But that's enough to make the air around it move to form a sound wave that we can hear.

I'll bet you know other devices that we use all the time to make electrical currents into sound. What about the other way around?

Support for Cornell Center for Materials Research is provided through NSF Grant DMR-0079992

One of the neatest features of your radio is that it gets all its power from the radio wave itself. It does all these jobs without being plugged into the wall or using a battery.

Here are a couple of views of one way to build your radio. The different sections are outlined in the second view to indicate by color the four main parts of the radio.

Using your radio:

Important Notes for Radio Builders and Parents

Antennas and Grounds and Warnings!!!

You'll need to connect your antenna and ground to the appropriate terminals through the clips on wires that you made up. Please be very careful not connect to live electric wires (conduit casing is fine for a ground however). Most importantly don't throw antenna wires over any utility cables: it is really really really dangerous if you get on an electric power wire. Also, don't ground to gas lines. Outdoor antennas are fine as long as they are temporary and are not left connected to your radio or house in times of possible lightning strikes. If you use a permanent outdoor antenna, you will need a lightning arrestor. A licensed electrician knows how to set one up, but that could be costly.

A swell ground is provided by a metal (not plastic, that won't conduct electricity!) cold water pipe. We have also had good luck with the metal nut on the outside of the cable connector for the local cable television service (be careful not to connect to the center conductor). You can make an antenna by stringing up your antenna wire as far as it will stretch. Outdoors it helps to get it off the ground, at least by a few feet. An antenna may also be provided by large pieces of metal such as a metal doorframe or rain gutter (again, think about the possibility of lightning and don't leave your set connected when not in use). One of the best antennas we have found is an air duct. For an outdoor birthday party, we found that a garden hose faucet made a swell ground. For the antenna, we found that a fine gauge magnet wire (like the #32 we use to wind our coils) sent up about 50' into a treetop by big Mylar helium balloon worked really well! The trick is to be patient and willing to experiment (for example try aiming the antenna in different directions). You should try to bite through paint with your clips to make contact with bare metal. It is possible however to connect by simply wrapping wire without making bare metal. Generally, avoid overlapping the antenna and ground wires. It will be fun to discover what works for you!

Tuning Your Radio:

Once you have set up an antenna and ground, just try turning the capacitor's knob. Good luck and have fun!

Trouble Shooting Defective Earphones

We have found that sometimes a good strong signal will fade away for no apparent reason while you are listening. If this happens to you, try rapping on the earphone (don't smash it so that it breaks! Striking with you finger with the force of a finger snap is the trick). We have found that doing this can quickly bring this back to life (you are likely to have to retune in case you moved the slug while trying to restore the signal). If this

Support for Cornell Center for Materials Research is provided through NSF Grant DMR-0079992
Copyright 2003 CCMR Educational Programs. All rights reserved.

happens to you, please let us know and we'll give you a replacement earphone in exchange for the defective one. We are pretesting our earphones, but you may still get a poor performer.

What to Listen for and When to Listen

You may be surprised to discover more stations at night than you can hear during the day. This is because the high reaches of the atmosphere can sometimes reflect radio waves from far way. If you're persistent, you may become an expert on this effect. Also, you may even pull in stations that are higher in frequency than the usual broadcast band.

More Information and Ideas for Home Experimentation

The World Wide Web is an amazing resource for more information on crystal radios and the crystal detector materials themselves. You can simply search under www.google.com for ``crystal radio.'' Here are some of the excellent sites you will find:

freeweb.pdq.net/headstrong/crystal.htm
www.midnightscience.com
http://www.scitoys.com/scitoys/scitoys/radio/radio
www.thebest.net/wuggy/build.htm

The wuggy website gives a great series of crystal radios under the link: The Project Crystal Radio. Our design is based on the second circuit.
The scitoys website of Simon Field is also not to be missed: his projects are exceptional in their fun, value and ease of building. As you will see, there are many marvelous variations and extensions to our current design. First, there are a great variety of antenna and ground possibilities. Within the radio itself, large tank coils can bring better performance both in signal strength and in ability to pick out one station at a time. You might wish to add a battery-powered one-transistor amplifier for portability (you will still need to have an antenna wire, but no ground is necessary). The regenerative receiver is an amazing few-transistor extension to provide extremely high sensitivity. With this design, you can readily detect waves with higher vibration rates (higher frequencies) that provide worldwide communication.

In order to modify your coil, you can pry it out of the glue that holds it to the base. You might prefer however to preserve your working radio and make a new one to try out a new design.

To learn more about the materials that make your radio work, you may enjoy books from a public library. Any edition of the ARRL's Handbook for Radio Amateurs will give you very useful information about what's inside your radio from the insulator inside your capacitor to the solder you used to make your set...

We look forward very much to news of your crystal radio experiences at home as well as any questions or stories to tell that you might have (grandparents know some of the most interesting radio tales). Our e-mail addresses are cpf1@cornell.edu and outreach@ccmr.cornell.edu.

Sincerely, Carl Franck, Juliane Bauer-Hutchinson, Nev Singhota, Kevin Dilley for the Cornell Center for Materials Research

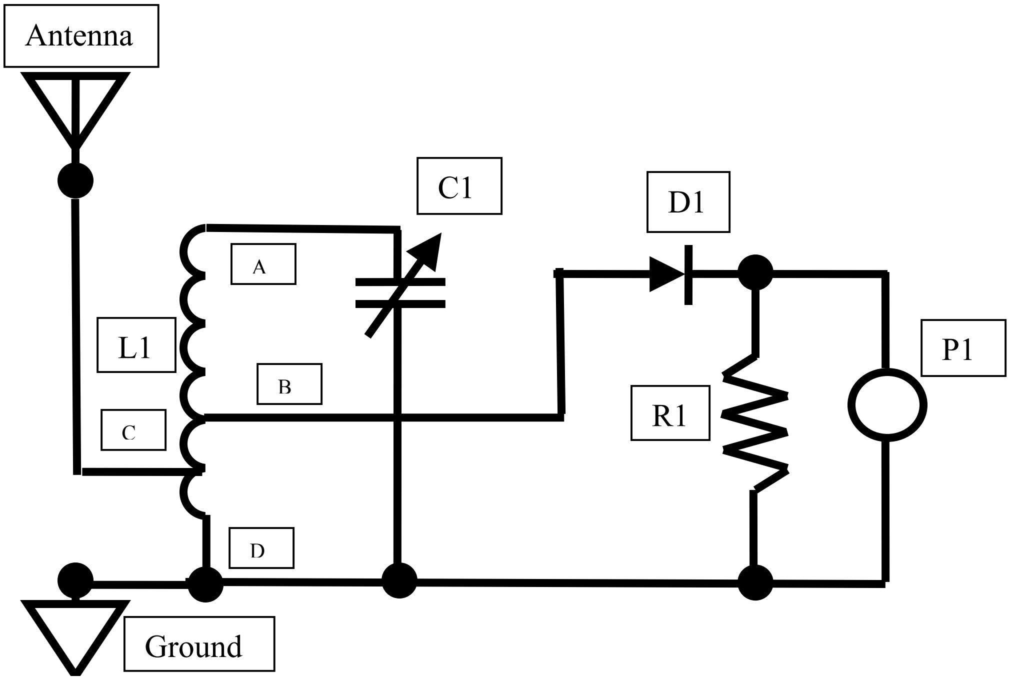
Radio-Builder's Diagram (Schematic)

Here's another way to understand how the various parts of your radio connect to each other. Radio builders call this a schematic. Each part has a special symbol. Wires are simply lines. We'll bet you can quickly find your fancy coil. Radio builders understand how the signals flow through your radio a lot more easily by looking at this diagram than the physical layout on the early pages. If you get a new idea to try out, you can explain to another radio builder easily by just drawing the new schematic. You might like to get some practice reading schematics by figuring out where our four sections of the radio are on this schematic. Good luck!



Antenna wire is 15' long medium sized clip on the end
Ground wire is 10' long with large clip on end

L1: Coil is 140 non-overlapping turns of #28 wire on 1.5" (inner diameter) thick walled PVC pipe (3" long) tapped at 20 and 40 turns from the ground side.

C1: 141(max) pf variable capacitor

D1: 1N34A diode

R1: 10K resistor

P1: piezoelectric earphone

Support for Cornell Center for Materials Research is provided through NSF Grant DMR-0079992
Copyright 2003 CCMR Educational Programs. All rights reserved.

Coil Winding Instructions

To wind the coil, tack the wire down with hot glue initially, wind five turns at a time side by side, taking up slack afterwards while compressing the coil after every set of five turns.

Starting from the bottom (wire connection D), wind 20 turns, bring out tap C, wind another 20 turns, bring out tap B, complete with 100 turns to end with connection A.

This version of the Make-A-Radio notes was made 7/28/03. C.F.

Eric's "Crystal Radio Initiative" Challenge 274

INTRODUCTION

As previously mentioned above, this book is currently the reordered compilation of posts in Energetic Forum, which were posted in response to Eric Dollard's Crystal Radio Initiative.

Who will be the first to light a 100 watt bulb from AM ground transmission and prove Tesla right and Einstein wrong? Even if you can only power a 7 watt bulb, you are definitely in the club as someone who has certainly made a point.

Please watch the video first that accompanies this Crystal Radio Initiative package, especially if you're a beginner. Write down a few of the strongest stations that you receive with this and pick one of those frequencies to design your Tesla style crystal radio for.

For the Tesla style crystal radio, you'll have to calculate the coil dimensions so it will be specifically tuned for one of the strongest stations that you receive with the regular crystal radio set.

Once you do this for a small scale Tesla style crystal radio, modify the circuit and try to light one of the very small midget flange bulbs as described in the video.

When you can accomplish that, you are ready to scale it up to try to light even bigger bulbs. As Eric Dollard mentioned in the video, if you can just get to the 7 watt size, then you have definitely proven the point.

Furthermore, you can compare the speed between the above ground reception and the telluric reception to see which is fastest. DR_GREEN has posted this recently in the Eric Dollard thread here: http://www.energeticforum.com/eric-dollard-official-forum/11855-eric-dollard.html - The below ground reception is faster than the light speed above ground transmission by the way. Not only will you be able to prove Tesla right, you'll be proving Einstein wrong.

Crystal Sets Gone Wild

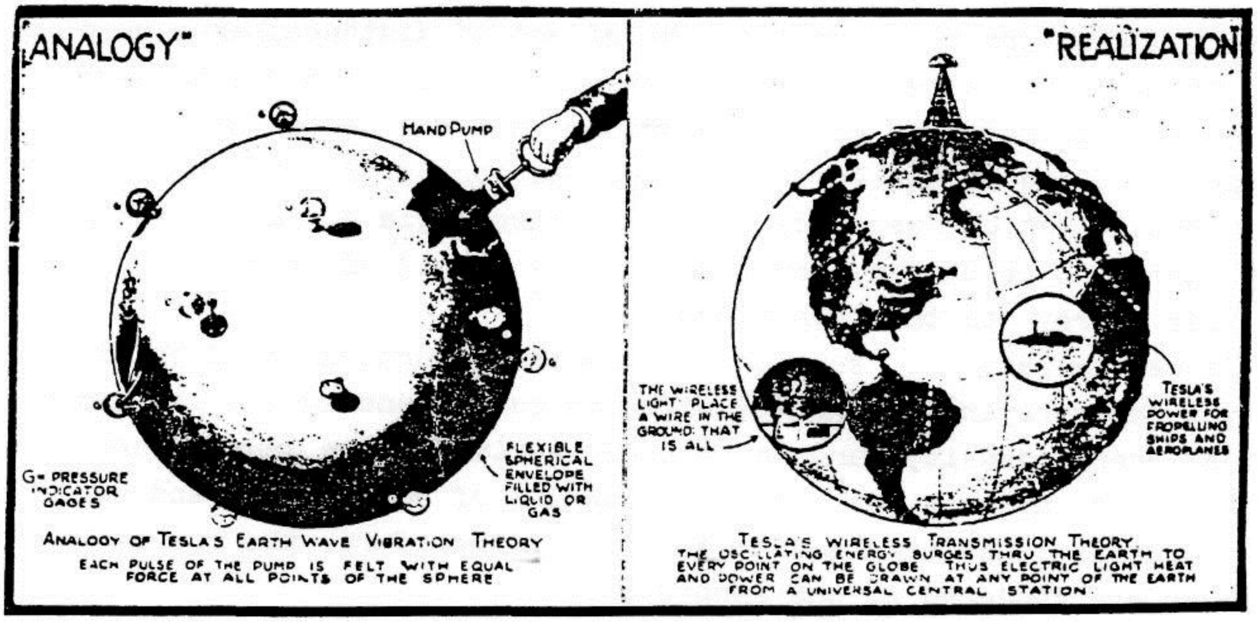
Crystal Sets Gone Wild

For the diagram shown the coil dimensions are missing, number of turns, etc. A good ground is essential for these kinds of devices. 16 Ground rods in a 10 to 20 foot radius circle, connected to a single ground rod at the center(17th rod), this connection being 10 gauge wire. Dry sand or rock will not ground, so this requires 80, each 14 gauge wires in a 30 foot diameter circle in a star radial configuration, to a center terminal. Without these groundings a Tesla Transformer cannot properly operate, but some "HI-Z" sets may.

The objective here is to scale the "Crystal Set", a step at a time, into a Tesla Transformer for the reception of medium wave band, 300 - 3000 kilocycle A.M. broadcasts. No license is required for this and the broadcast station provides the power.

And this objective cooperates with the primary objective. That is; Who will be the first ham to disprove Einstein's theory? An International contest, but who will sponsor it, Iran maybe?

We have the good fortune in the "Crystal Set Initiative" that, in theory at least, a quarter wave A.M. broadcast tower, and its 120 quarter wave ground radials, must emit a pair of waves as shown by Tesla in his basic diagrams.



"ANALOGY"
HAND PUMP
G= PRESSURE INDICATOR GAGES

C2
C1 ≈ 1500 pFd
C2 ≈ 500 pFd
C3 ≈ 100 pFd
Co ≈ 10 pFd
LC = T², @ 1000 Kc/sec

Hence it can be seen that a pair of waves are engendered by this transmission system. (Tower and Star Radials). One wave, Hertzian, is the over ground wave, the other wave, Telluric, is the under ground wave. These two waves arrive at the point of reception in their own distinct time frames, giving rise to a difference in phase. Hence, multiple rings of interference patterns are produced. Since the Hertzian portion, over ground, time frame is based upon the velocity of light, then the Telluric portion, under ground, time frame gives the Telluric velocity. Two crystal sets, one over ground, one under ground, and a basic oscilloscope , that simple. I have done this at Landers.

Concluding, a Tesla Magnification Transformer, properly proportioned can, in theory, actually draw power from a local 50 kW station. Several hundred watts of power reception is likely. This would prove Tesla once and for all. No antenna, just a good ground, and a nice and bright 100 watt light bulb.

This would overturn physics more than any billion dollar C.E.R.N. project. A ham radio operator overturns Einstein for 100 bucks. What a concept.

Notes on the Crystal Set

Notes on the Crystal Set

When measuring the velocity difference between underground and our ground, the two seperate receivers can be brought into phase unison by the use of a test oscillator. Both receivers must have a primary tank circuit, here you can place your measurement equipment.

The detected AM output, audio frequency, signal is immune to receiver phase shift. This is a property of A.M. detection. Use the audio to measure propagation delay.

Wind all coils in the same direction, this is a must! Brass is a very good primary material, good depth of penetration at broadcast frequencies. Wires and clip lead interconnection are the "Road to Absolute Defeat." Coils and Condensers must be merged into each other in broad surfaces. Stacked metal plates on insulators makes good condensers. Transmitter air condensers are good, vacuum condensers are the best. A number of small condensers are better than one big one, less stray inductance. Stray inductance is fatal to success! For smaller units silver mica condensers are the only way, use no others. Paralell them on a low inductance bus.

Do not get sidetracked, experimental and auxilliary coils as well as patent diagrams will get you stuck in the sand forever. The finished Colorado unit dimensions are all in the notebook. It is all there, look at it, not the diversions, and remember everything you thought was Tesla is the exact opposite. It is there; one or two turn primary; a 20% height/width secondary; and a 100% height/width extra coil, all there, wire size, turns, all there, can you find it? It then can be scaled to any frequency and any KVAR capacity within wavelength conditions.

As your unit gets perfected the signal gets stronger and stronger, then diodes start burning out. We then are reaching the engineering objective, that is to light a number 327 pilot lamp. Not much power but too bright for Einstein.

Tesla Type Crystal Radio

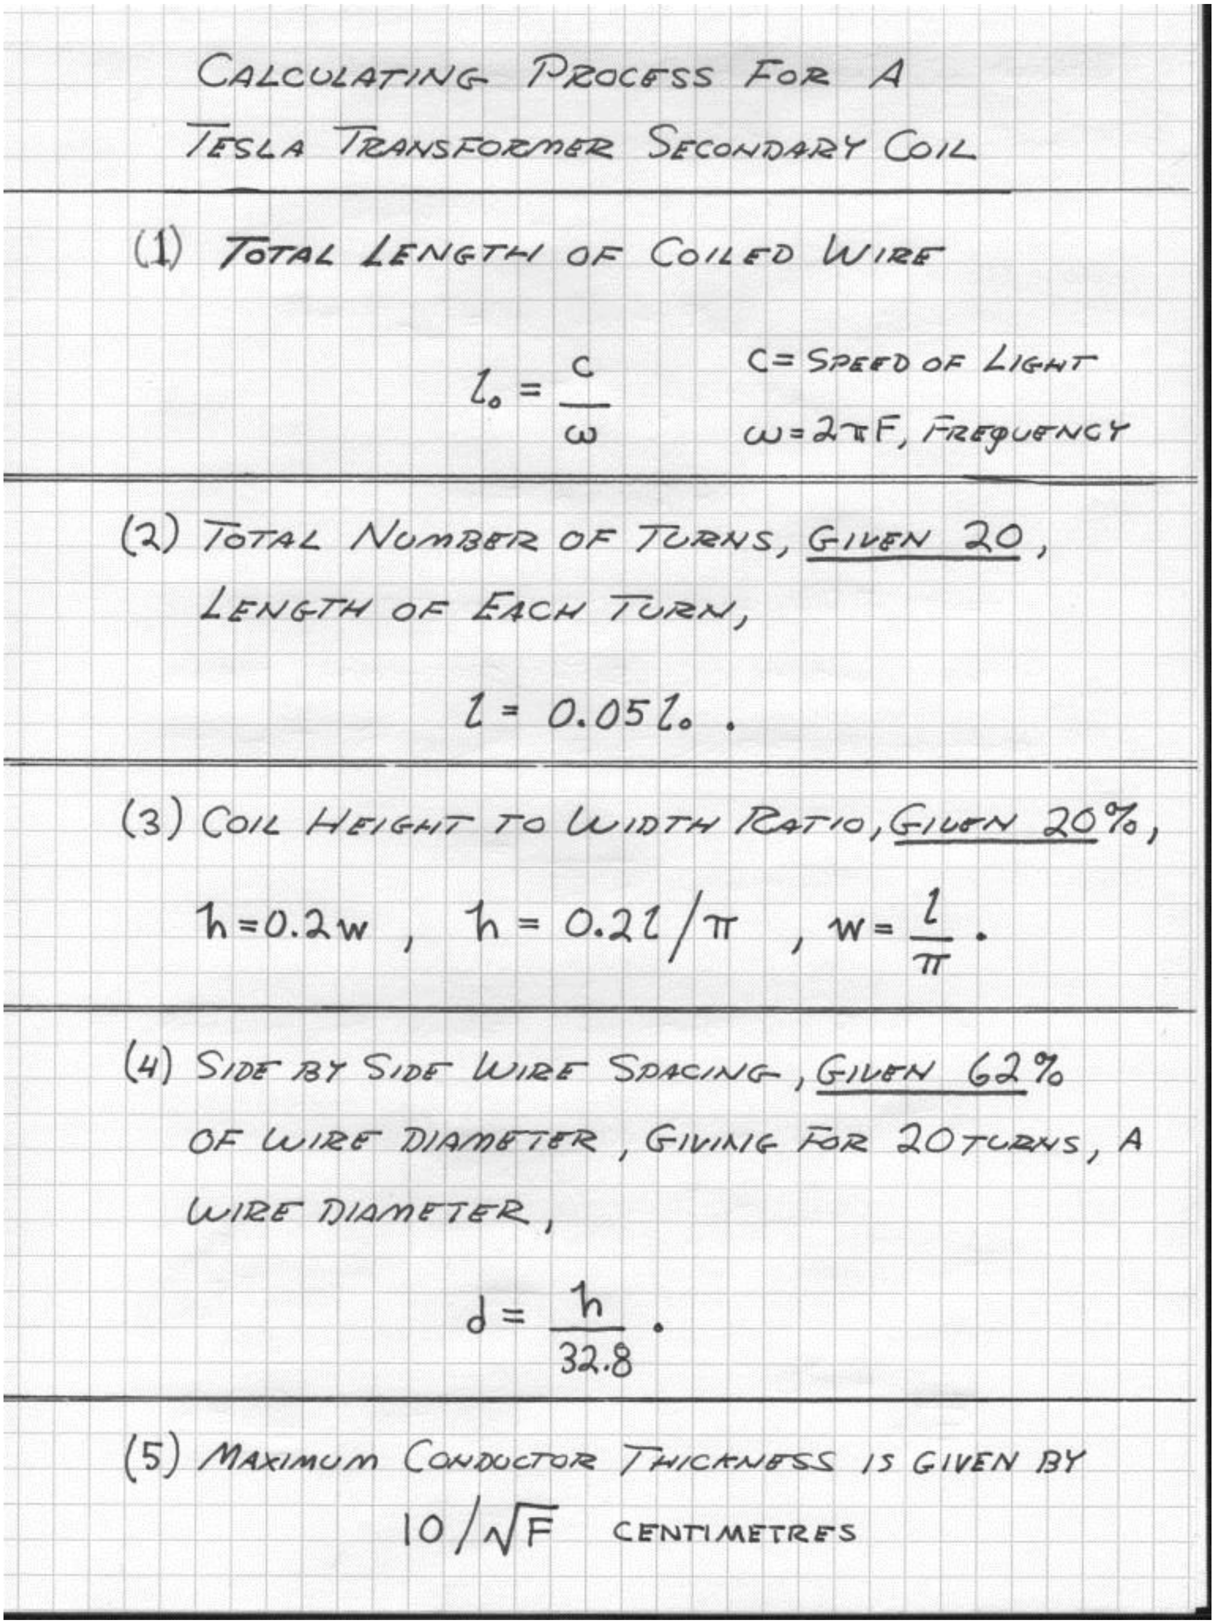
The design of the Tesla Transformer starts with the secondary resonant coil. In its resonant mode it is a quadrapolar resonator. Two constants exist in the construction of this solenoidal resonator, one is that the height to length ratio must be 20%, the other is that the side by side spacing of the cylindrical conductor turns is 62% the diameter of the cylindrical conductor. The optimum number of turns is 20 on the secondary, with 2 on the primary. This gives the physical size of the coil for a given frequency. Increasing the number of turns reduces the size of the secondary coil in proportion to the increase in turns. Accordingly the conductor diameter also decreases as the copper is spread out over more windings. The ratio of secondary turns to primary turns must equal a constraint of 10 to 1. For a given number of turns the operating frequency becomes the sole independent variable in coil design.

The primary coil is the same diameter as the secondary coil. The ratio of conductor width to coil diameter is 18%. The sheet conductor is closely spiralled into two turns, for a secondary of twenty turns. For a conductor thickness as given by the maximum thickness vs frequency the volume of the primary metal must equal the volume of the secondary metal, based upon equal weights for primary and secondary metals. Brass can be 1.7 times thicker than copper, and bronze can be 2.8 times thicker than copper, for a given maximum thickness and frequency.

The primary condenser should be made of the same amount of metal as the primary coil. Their weights should be about the same. The connecting leads must be short and the same width as the primary conductor. Large, multiplate air condensers are good, so are metal sheets and glass.

The secondary capacitance is best a copper tubing ring around the outside of the H end of the coil. This ring must be open in one spot along its loop so as not to be a shorted turn. The end of the secondary wire connects to this capacity ring. Beer cans make the best elevated capacitors.

The finished transformer must operate on a directly connected ground plane. A large plywood table with aluminum foil glued on to it, this covered with a plastic or glass sheet is the minimum required ground plane. Obviously the aluminum plane must be solidly earthed with special attention to minimizing ground lead inductance. In order to light a lamp a more broadcast station style of ground plane is required, but for testing purposes the metallized plywood "ten by" sheet is just fine. Good luck and good crystal set DX ing.



CALCULATING PROCESS FOR A TESLA TRANSFORMER SECONDARY COIL

(1) TOTAL LENGTH OF COILED WIRE

$$l_0 = \frac{c}{\omega}$$

C = SPEED OF LIGHT

$\omega = 2\pi F$, FREQUENCY

(2) TOTAL NUMBER OF TURNS, GIVEN 20,
LENGTH OF EACH TURN,

$$l = 0.05\,l_0 .$$

(3) COIL HEIGHT TO WIDTH RATIO, GIVEN 20%,

$$h = 0.2w \quad , \quad h = 0.2l/\pi \quad , \quad w = \frac{l}{\pi} .$$

(4) SIDE BY SIDE WIRE SPACING, GIVEN 62%
OF WIRE DIAMETER, GIVING FOR 20 TURNS, A
WIRE DIAMETER,

$$d = \frac{h}{32.8} .$$

(5) MAXIMUM CONDUCTOR THICKNESS IS GIVEN BY

$10/\sqrt{F}$ CENTIMETRES

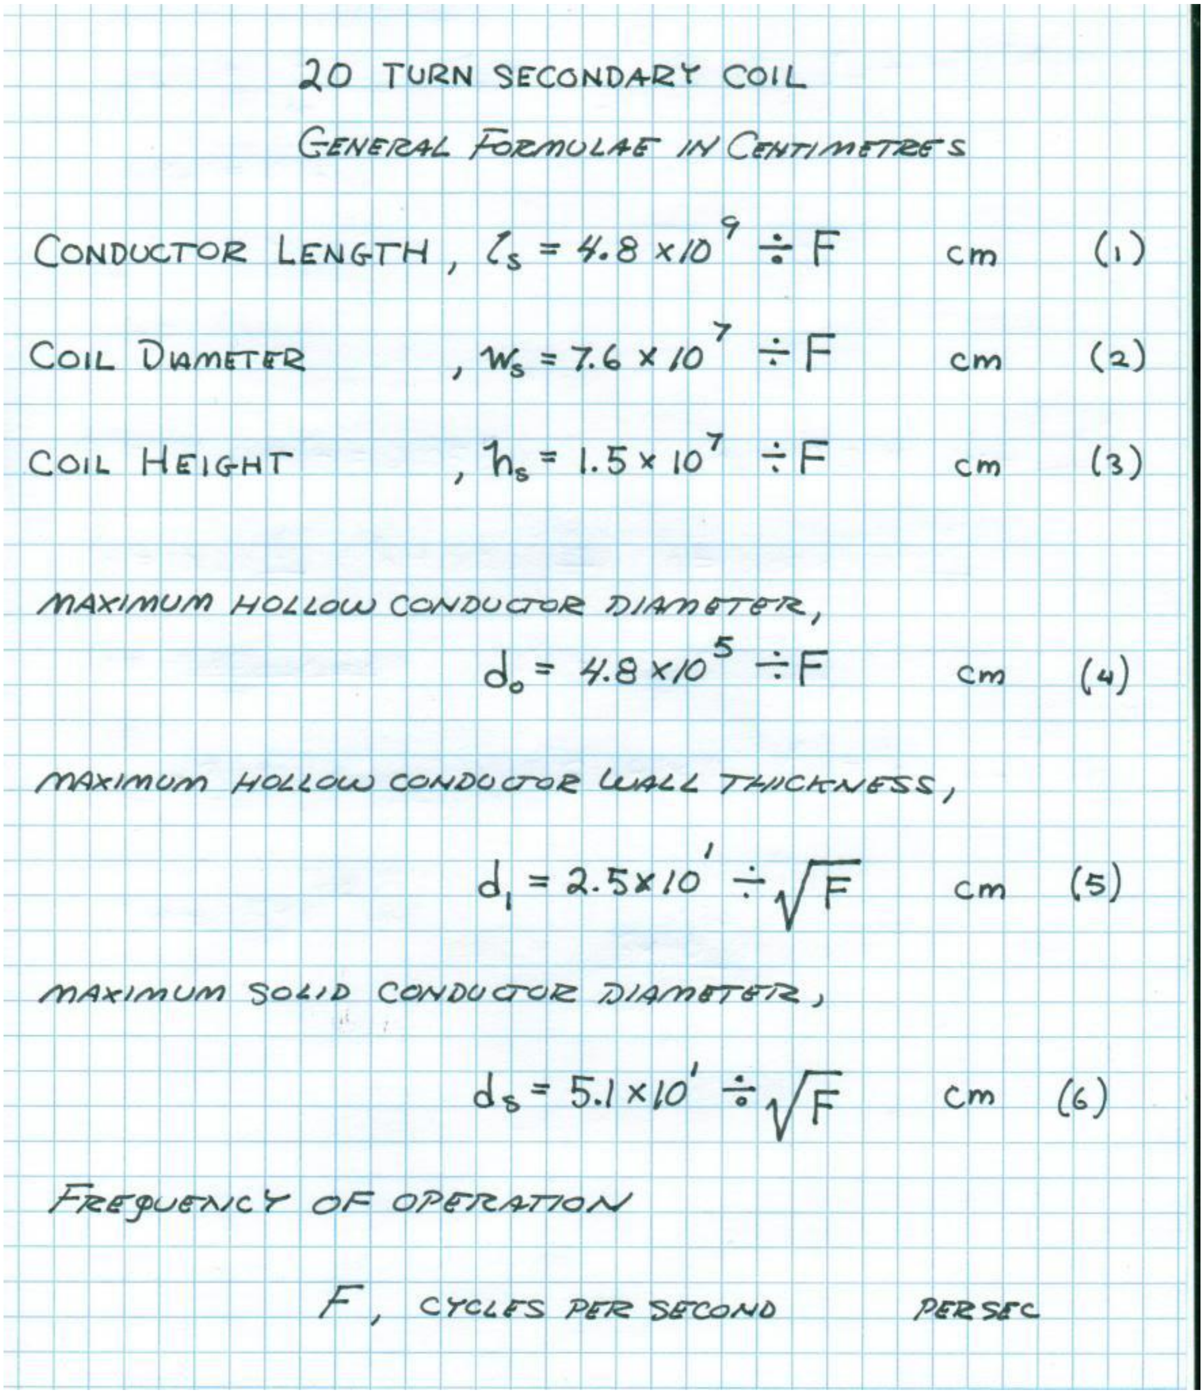
Using these:



20 TURN SECONDARY COIL

GENERAL FORMULAE IN CENTIMETRES

CONDUCTOR LENGTH, $l_s = 4.8 \times 10^9 \div F$ cm (1)

COIL DIAMETER, $w_s = 7.6 \times 10^7 \div F$ cm (2)

COIL HEIGHT, $h_s = 1.5 \times 10^7 \div F$ cm (3)

MAXIMUM HOLLOW CONDUCTOR DIAMETER,

$d_0 = 4.8 \times 10^5 \div F$ cm (4)

MAXIMUM HOLLOW CONDUCTOR WALL THICKNESS,

$d_1 = 2.5 \times 10^1 \div \sqrt{F}$ cm (5)

MAXIMUM SOLID CONDUCTOR DIAMETER,

$d_s = 5.1 \times 10^1 \div \sqrt{F}$ cm (6)

FREQUENCY OF OPERATION

F, CYCLES PER SECOND PER SEC

TENTATIVE EXTRA COIL DIMENSIONS

(1) CONDUCTOR LENGTH , $l_e = \frac{\pi^2}{4} l_s$

(2) COIL DIAMETER , $W_e = 0.4 W_s$

(3) LENGTH OF TURN , $l_1 = \pi W_e$

(4) ACTIVE COPPER DIA , $\delta_e = \frac{4}{\pi^2} \delta_s$

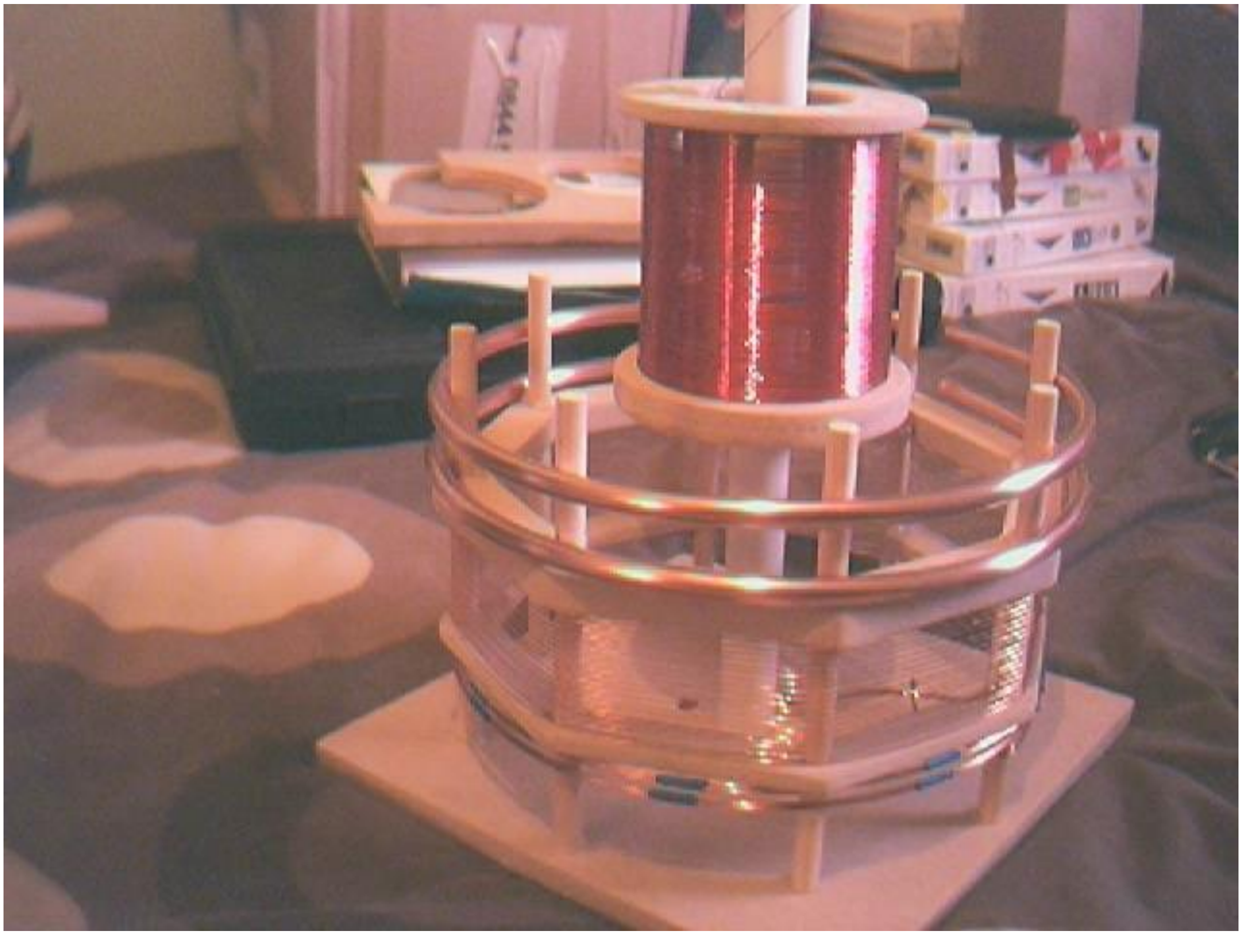
(5) MAX WIRE SIZE , $d_e = d_s$

(6) NUMBER OF TURNS , $N = \frac{l_s}{l_1}$

(7) CONDUCTOR SPACING , $s = \frac{d - N}{N-1}$

d , CONDUCTOR DIAMETER

l_s W_s etc. , SECONDARY LENGTHS



F = 3670000 cycles/sec

Secondary
Height = 4.08cm
Diameter = 20.7cm
Number of turns = 20
Wire = 13 +/- metres 26 SWG (thin wire issues resulting in slight octagon shape therefore reduced length, estimated actual length = approx 12.92 metres)
Approx 18.9 grams of copper in coil

Extra coil
Height = 8.28cm
Diameter = 8.28cm
Number of turns = 126
Wire = 32.27 metres 26 SWG (advisable not to use thicker wire otherwise no room on coil frame, impossible to space 126 turns evenly as is)

Margin of error between calculated and measured frame dimensions after construction = <0.5mm

Primary
2 turns, not flat spiral
Wire = 2 x 20 SWG + 24 SWG parallel wound

Tests results = Forthcoming

C.R.I. Questions and Answers

Post numbers here refer to the Crystal Radio Magic Thread

Post 73, Jake.

Standing wave on coil indicates proper operation. A voltage node must exist exactly at the neutral terminal. Tesla could move this node about in the earth. This is important and in an optimum state the voltage node is right at the point of earthing. A projected wave velocity exist on the earth surface, infinite at the earth connection, and luminal 90 degrees around the planet. It is a tangent function with Pi over two as the "Effective velocity". Hence velocity here is only a projection on the earth surface, not a true velocity, like your shadow at sundown it goes to infinity.

Post 136, Madhatter.

The B field is a bad way to look at this. It is a physics dingleberry. B is a dimensional relation with a per centimetre square. Here it is best to use versor magnetic induction k Phi, see last part of Theory of Wireless Power. Mutual inductance is longitudinal so that coupling remains for concatenated longitudinal resonators. Wave direction now has a role in coupling.

Post 143, Madhatter

Wave direction coupling makes balance to unbalance transformation impossible, this gives the "dead phase" extra coil. If it is a balanced system, every part of that system must be push-pull. Unbalanced unit has neutral on one side of primary, a balanced unit has neutral on primary center tap. All concatenated coils must be wound in same direction as wave propogation spiraling around them.

Post 156, Jake

Do not replace 100 pF condenser with LED, it will distort and rob power from the audio. Use a completely separate setup for LED. Try Ne 2 neon lamps. Also a 10-15 watt fluorescent lamp is a good standing wave "wand", this for tuning.

I would recommend using a 6SN7 Triode section with cathode drive from function generator and the primary as the plate tank circuit. See the figure. This will greatly improve resonance for tuning. 50 Ohm across primary NFG, 6SN7>6000 Ohm general.

Multiple tuning peaks indicate overly tight coupling between coils. Slowly separate them until only one resonant peak. Multiple modes of stray reception and strong local stations will make grounding and tuning very confusing. An isolation amplifier 6SN7 triode isolates amplifier from function generator interaction and gives more power to light neon lamps. Both sections of 6SN7 in parallel give more power.

WHAT ABOUT TODAY'S SCIENTISTS?

"The scientists from Franklin to Morse were clear thinkers and did not produce erroneous theories. The scientists of today think deeply instead of clearly. One must be sane to think clearly, but one can think deeply and be quite insane.

"Today's scientists have substituted mathematics for experiments and they wander off through equation after equation and eventually build a structure which has no relation to reality."

- Nikola Tesla -

The Oscillating Current Transformer

The oscillating current transformer functions quite differently than a conventional transformer in that the law of dielectric induction is utilized as well as the familiar law of magnetic induction. The propagation of waves along the coil axis does not resemble the propagation of waves along a conventional transmission line, but is complicated by inter-turn capacitance & mutual magnetic inductance. In this respect the O.C. transformer does not behave like a resonant transmission line, nor a R.C.L. circuit, but more like a special type of wave guide. Perhaps the most important feature of the O.C. transformer is that in the course of propagation along the coil axis the electric energy is dematerialized, that is, rendered mass free energy resembling Dr. Wilhelm Reich's Orgone Energy in its behavior. It is this feature that renders the O.C. transformer usefull for wireless power transmission and reception, and gives the O.C. transformer singular importance in the study of Dr. Tesla's research.

FUNDAMENTALS OF COIL INDUCTION

Consider the elemental slice of a coil shown in fig. 1. Between the turns 1,2 & 3 of the coiled conductor exists a complex electric wave consisting of two basic components. In one component (fig. 2), the lines of magnetic and dielectric flux cross at right angles, hereby producing a photon flux perpendicular to these crossings, hereby propagating energy along the gap, parallel to the conductors and around the coil. This is the transverse electro-magnetic wave. In the other component, shown in fig. 3, the lines of magnetic flux do not cross but unite along the same axis, perpendicular to the coil conductors, hereby energy is conveyed along the coil axis. This is the Longitudinal Magneto-Dielectric Wave.

2
3
SLICE OF COIL WINDING, THREE TURNS

FIGURE (1)

Hence, two distinct forms of energy flow are present in the coiled conductor, propagating at right angles with respect to each other, as shown in fig. 4. Hereby a resultant wave is produced which propagates around the coil in a helical fashion, leading the transverse wave between the conductors. Thus the oscillating coil posses a complex wavelength which is shorter than the wavelength of the coiled conductor.

COIL CALCULATION

If the assumptions are made that an alternating current is applied to one end of the coil, the other end of the coil is open circuited. Additionaly external inductance and capacitance must be taken into account, then simple formulae may be derived for a single layer solenoid.

The well known formula for the total inductance of a single layer solenoid is

$$L = \frac{r^2 N^2}{(9r+10l)} \quad x\ 10^{-6}\ \text{Henry (inches)} \qquad (1)$$

Where r is coil radius
l is coil length
N is number of turns

May-June 1986 JBR, Page 18

The capacitance of a single layer solenoid is given by the formula

$$C = pr \quad 2.54 \times 10^{-12} \text{ Farads (inches)} \qquad (2)$$

where the factor p is a function of the length to diameter ratio, tabulated in table (1). The dimensions of the coil are shown in figure (1). The capacitance is minimum when length to diameter ratio is equal to one.

Because the coil is assumed to be in oscillation with a standing wave, the current distribution along the coil is not uniform, but varies sinusoidially with respect to distance along the coil. This alters the results obtained by equation (1), thus for resonance

$$L_o = \tfrac{1}{2}L \qquad \text{Henrys} \qquad (3)$$

likewise, for capacitance

$$C_o = \frac{8}{\pi} C \qquad \text{Farads} \qquad (4)$$

Hereby the velocity of propagation is given by

$$V_o = 1/\sqrt{L_o C_o} = \eta V_c \qquad \text{Units/sec} \qquad (5)$$

Where

$$V_c = 1/\sqrt{\mu \varepsilon} \qquad \text{Inch/sec} \qquad (6)$$

That is, the velocity of light, and

$$V_o = V_c \eta = \left[\frac{1.77}{p} + \frac{3.94}{p} n\right]^{\frac{1}{2}} 2\pi 10^9 \qquad \text{Inch/sec} \qquad (7)$$

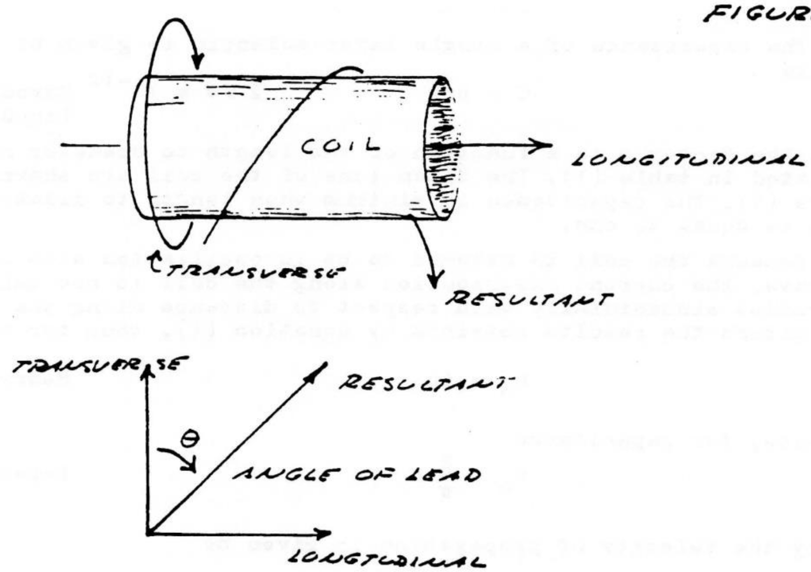
Where n = the ratio of coil length to coil diameter. The values of propagation factor η are tabulated in table (2).

Thus, the frequency of oscillation or resonance of the coil is given by the relation

$$F_o = V_o/(l_o \cdot 4) \qquad \text{Cycles/sec} \qquad (8)$$

Where l_o = total length of the coiled conductor in inches.

FIGURE (4)



The characteristic impedance of the resonant coil is given by

$$Z_c = \sqrt{\frac{L_o}{C_o}} \qquad \text{Ohms} \qquad (9)$$

Hence,

$$Z_o = NZ_s \qquad \text{Ohms} \qquad (10)$$

Where

$$Z_s = \left[(182.9 + 406.4n)p\right]^{\frac{1}{2}} \qquad \frac{\pi}{2}\,10^3 \qquad \text{Ohms (inches)} \qquad (11)$$

and N = number of turns. The values of sheet impedance, Z_s, are tabulated in table (3).

The time constant of the coil, that is, the rate of energy dissipation due to coil resistance is given by the approximate formula

$$u = R_o/2L_o = \left(\frac{2.72}{r} + \frac{2.13}{l}\right)\pi\sqrt{F_o} \qquad \text{Nepers/sec (inches)} \qquad (12)$$

Where r = coil radius
l = coil length

In general, the dissipation of the coil's oscillating energy by conductor resistance:

1) Decreases with increase of coil diameter, d;
2) Decreases with increase of coil length, l, rapidly when the ratio, n, of length to diameter is small with little decrease beyond n equal to unity;
3) Is minimum when the ratio of wire diameter to coil pitch is 60%.

By examination of the attached tables, (1), (2) & (3), it is seen that the long coils of popular designs do not result in optimum performance. In general, coils should be short and wide, and not longer than n=1. The frequency is usually given as $F_o = V_c/\lambda_o$ which by equation (7) is incorrect. Winding on solid or continous formers rather than spaced slender rods, as shown in figure (1), greatly retards wave propagation as indicated in equation (6), thereby seriously distorting the wave. The dielectric constant of the coil, ε , should be as close to unity as is physically possible to insure high efficiency of transformation.

The equations for the voltampere relations of the oscillating coil are

$$\dot{E}_1 = j\,(Z_c\,Y_o + \delta)\,\dot{E}_o \qquad \text{Complex Input Voltage} \qquad (13)$$

$$\dot{I}_1 = j\,(Y_c\,Z_o + \delta)\,\dot{I}_o \qquad \text{Complex Input Current} \qquad (14)$$

$$Z_1 = \frac{Z_c\,Y_o + \delta}{Y_c\,Z_o + \delta}\,Z_o \qquad \text{Input Impedance, Ohms} \qquad (15)$$

Where

$\dot{E}_o$ = Voltage on elevated terminal

$\dot{I}_o$ = Current into elevated terminal

$Y_c = Z_c^{-1}$

Z_o = Terminal impedance

Y_o = Terminal admittance

$\delta = u/2F_o$ = Decrement

j = root of $\sqrt{-1}$

For negligible losses and absolute values

$$E_1 = (Z_c 2\pi F_o C_o)E_o \qquad \text{Volts} \qquad (16)$$

$$I_1 = (Y_c/2\pi F_o C_o)I_o \qquad \text{Amperes} \qquad (17)$$

Where

C_o = **Terminal capacitance**

By the law of conservation of energy

$$E_1 I_1 = E_o I_o \qquad \text{Volt-Amperes} \qquad (18)$$

If the terminal capacitance is small then the approximate input/output relations of the Tesla coil are given by

$$E_o = Z_c I_1 \qquad \text{Output Volts} \qquad (19)$$

$$I_1 = E_o Y_c \qquad \text{Input Amperes} \qquad (20)$$

$$I_o = Y_c E_1 \qquad \text{Output Amperes} \qquad (21)$$

$$E_1 = I_o Z_c \qquad \text{Input Volts} \qquad (22)$$

Comment and Correction

The following is the corrected version of the equations given in post #404.

Equations (1) and (2) still need to be substituted into equations (6), (7), and (9). Graphs should be made up also. Can someone do this and also reprint in better form the following equations. Next, taking the data from the COlorado notes, these equations should be applied to the final Colorado design, here for all to see, u, Z, etc.

Also the Guillemen line is IMPORTANT, the rest of the MIT pages on it would be helpful here. The Guillemen line is a "single wire" longitudinal transmission structure. Hence it is an analog of a longitudinal wave, or a section of a one wire transmission system. This is known as a "two terminal" network, in distinction to the standard "four terminal" network. Guillemen's rearrangement of the condensers from shunt to series greatly reduced the dielectric stress on these condenser. This allowed for a great reduction of size and weight, important for aircraft. The smallest thermionic gas thyratron suitable for impulse work is the 2050. It is an argon type so not very fast. The smallest hydrogen thyratron is the 3C45. It likes about 1500 volts DC.

As for gas diode tubes of the cold cathodes DC type is the,

OA3, 75 volt neon
OB3, 90 volt argon
OD3, 150 volt helium

and the cold cathode detector triode is the OA4G (neon).

These tube types are usually plentiful and cheap. The OA4G may be a bit hard to find however. There are several miniature types of cold cathode triodes in existence but I do not remember the numbers. I would point out here that blowing them up is not very useful, they do not make them anymore.

Finally, rather than an endless string of experiments doing "strange things" more might be gained by developing a solid theoretical concept of what we are getting into. And for the "free energy fuse box" crowd, forget it. No one is going to use wireless power transmission so she does not have to see the power line to her new "dream home" on top of the hill. Transmission of radio frequency energy for any purpose is subject to government approval, no way around it. Remember that the excuse Franklin Roosevelt, USN used to

outlaw radio was the mess of jamming and interference created by electrical experimenters leading up to 1917, the day that wireless died. This can happen again in the 911 police reality, watch out.

73 DE N6KPH

RE-WORKED AND CORRECTED FORMULAE FOR COIL CALCULATION

(1) FORMULA FOR SCALAR INDUCTANCE OF A SINGLE LAYER SOLENOID.

$$L_0 = \frac{r^2 N^2}{9r + 10l} \times 10^{-6}$$

WHERE L_0 IS THE TOTAL INDUCTANCE IN HENRY

N IS THE NUMBER OF TURNS

r IS THE COIL RADIUS IN INCHES

l IS THE COIL LENGTH IN INCHES.

(2) FORMULA FOR THE SELF CAPACITANCE OF A SINGLE LAYER SOLENOID.

$$C_0 = \rho r \qquad 2.54 \times 10^{-12}$$

WHERE, C_0 IS IN FARAD, r, IS THE RADIUS IN INCHES

ρ IS A PROPORTION FROM TABLE (1)

THE PROPORTION FACTOR IS A FUNCTION OF THE COIL ASPECT RATIO. SEE "SELF CAPACITANCE OF COILS", RADIOTRON DESIGNER HANDBOOK.

HENCE DERIVED IS THE "STATIC" INDUCTANCE AND CAPACITANCE IN THE DIMENSION OF INCHES.

COIL INDUCTANCE, L_0, HENRY (INCH)

COIL CAPACITANCE, C_0, FARAD (INCH)

BECAUSE THE COIL IS IN A PI OVER TWO OSCILLATION THE EFFECTIVE VALUES OF L_0 AND C_0 ARE ALTERED BY A STANDING WAVE.

THE FOLLOWING EFFECTIVE VALUES ARE GIVEN BY:

"OSCILLATIONS, IN ANTENNAE AND INDUCTION COILS", J. MILLER, 1919.

THE EFFECTIVE INDUCTANCE IS GIVEN BY

(3) $$L = \frac{1}{2} L_0$$ HENRY, AND

(4) $$C = \frac{8}{\pi^2} C_0$$ FARAD.

IS THE EFFECTIVE CAPACITY OF THE COIL.

THE EFFECTIVE VELOCITY IS GIVEN BY THE RELATION

(5) $$u^2 = \frac{1}{LC}$$

UNITS PER SECOND

$$u = \frac{1}{\sqrt{LC}}$$

THIS IS NOT AN ACTUAL VELOCITY IN THE NORMAL SENSE. HERE u IS A PROPORTION BETWEEN WINDING LENGTH AND FREQUENCY.

THE LUMINAL VELOCITY IN THE SPACE OCCUPIED BY THE SOLENOIDAL COILED WINDING IS GIVEN BY

(6) $$v^2 = \frac{1}{\mu \epsilon}$$

$$v = \frac{1}{\sqrt{\mu \epsilon}}$$

INCHES PER SECOND

THE PI OVER TWO RESONANT FREQUENCY OF THIS SOLENOIDAL COILED WINDING IS GIVEN BY

(7) $$F_o = \frac{u}{4 \ell_o}$$

CYCLES PER SECOND

WHERE ℓ_o IS THE TOTAL LENGTH OF COILED WIRE IN INCHES.

THE RATIO OF THE EFFECTIVE VELOCITY, u, AND THE LUMINAL VELOCITY, v, GIVES THE PERCENTAGE INCREASE OVER THE VELOCITY OF LIGHT AXIALLY ALONG THE WIRE AXIS.

(8) $$\frac{u}{v} = \eta$$ PERCENT

OR $$u = \eta v$$ INCH PER SECOND.

WHERE

$u < v$, SLOWER THAN LIGHT

$u > v$, FASTER THAN LIGHT

THE NATURAL, OR CHARACTERISTIC, IMPEDANCE OF THE COILED WINDING IN PI OVER TWO OSCILLATION IS GIVEN BY

(9) $$Z_0^2 = \frac{L}{C}$$

$$Z_0 = \sqrt{\frac{L}{C}}$$ OHM

AND RELATING TO THE NUMBER OF TURNS

$$Z_0 = N Z_s$$ OHM

WHERE N IS THE NUMBER OF TURNS

Z IS THE "SHEET IMPEDANCE".

From Radiotron Designers Handbook

At frequencies between 2 and 6 Mc/s (which are used in receivers providing continuous coverage between the normal short-wave and broadcast bands, or for oscillators giving second harmonic mixing for the short wave band) the progressive universal winding is particularly useful because the winding length of solenoids may be too great with the usual range of former diameters, and the number of turns is insufficient to allow them to be split into many sections.

A set of worm driving gears which spreads the appropriate number of turns over a length approximately equal to the coil diameter is required. This usually necessitates a faster worm drive than is used for broadcast coils. Litz wire with a large number of strands is useful in obtaining maximum Q.

For the 6 to 18 Mc/s band the solenoid is used, almost always with solid wire, and this type of coil remains useful at least up to 100 Mc/s. Increased wire diameters and spacings are used at higher frequencies to obtain form factors similar to those used at low frequencies.

SECTION 2: SELF-CAPACITANCE OF COILS

(i) Effects of self-capacitance (ii) Calculation of self-capacitance of single-layer solenoids (iii) Measurement of self-capacitance.

(i) Effects of self-capacitance

The self-capacitance of a coil is due to the electrostatic coupling between individual turns and between the turns and earth. When the self-capacitance is between uninsulated turns in air its Q may be high, but the greater the amount of dielectric in the field of the coil the greater will be the losses.

Short wave coils of enamelled wire on a solid former do not have serious dielectric losses if good quality materials are used, but at broadcast and intermediate frequencies the universal windings used have comparatively high-loss dielectrics and unless self-capacitances are kept to a low value the reduction in Q may be appreciable.

In the case of coils which are to be tuned over a range of frequencies, comparatively small values of shunt capacitance can have a large effect on the possible tuning range.

In all cases the self capacitance of a coil has an apparent effect on its resistance, inductance and Q, and at frequencies considerably below the self resonant frequency of the coil—

$$\text{apparent inductance} = L\left(1 + \frac{C_0}{C}\right)$$

$$\text{apparent resistance} = R\left(1 + \frac{C_0}{C}\right)^2$$

$$\text{and apparent } Q = Q/\left(1 + \frac{C_0}{C}\right)$$

where C_0 = self-capacitance of coil
C = external capacitance required to tune L to resonance
L = true inductance of coil
R = true resistance of coil
and Q = true Q of coil.

(ii) Calculation of self-capacitance of single-layer solenoids

Until recently the work of Palermo (Ref. C3) had been taken as the standard on the self-capacitance of single-layer solenoids. However Medhurst (Ref. C2) has disputed the theoretical grounds on which Palermo's work is based. As the result of a careful analysis and a large number of measurements he states that the self-capacitance, C_0, of single-layer solenoids with one end earthed, and without leads, is

$$C_0 = HD \ \mu\mu\text{F} \qquad (1)$$

where D = diameter of coil in cm.

and H depends only on the length/diameter ratio of the coil. A table of values of H is given below and when used in conjunction with a capacitance correction for the "live" lead, Medhurst states that the accuracy should be within 5%.

TABLE 1

(iii) Measurement of self-capacitance

A graphical method of self-capacitance determination due to Howe is shown in Fig. 11.2. Values of external capacitance in $\mu\mu$F required to tune a coil to resonance are plotted against $1/f^2$ where f is the resonant frequency in Mc/s. The self-capacitance is the negative intercept of the straight line with the capacitance axis.

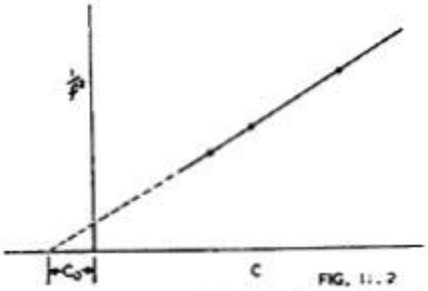

Fig. 11.2. *Construction for determination of self-capacitance of coil.*

An alternative method is to determine the external capacitances necessary to tune a coil to frequencies of f and $2f$. If the two capacitances are C_1 and C_2 respectively,

$$\text{self-capacitance} = \frac{C_1 - 4C_2}{3}.$$

SECTION 3 : INTERMEDIATE-FREQUENCY WINDINGS

(i) Air-cored coils (ii) Iron-cored coils (iii) Expanding selectivity i-f transformers (iv) Calculation of gear ratios for universal coils (v) Miscellaneous considerations.

(i) Air-cored coils

Most commercial receivers have two i-f transformers with four circuits tuned to about 455 Kc/s. To obtain adequate selectivity in such a case the required Q for each winding (mounted on the chassis but not connected in the circuit) is 100 or more.

This Q can readily be obtained with air cored coils of about 1 mH inductance provided that litz wire and comparatively large coil cans are used. Without litz it is difficult to exceed a Q of 50, but even this may be sufficient when more i-f stages than usual are used.

When a single pie is used, Q is to some extent dependent on coil shape but if five times the winding depth plus three times the winding width equals the external diameter, Q will be close to the maximum for the wire and type of winding.

There are three methods of increasing the Q, and when all are used to practical commercial limits, production Q figures of 150 can be maintained. The first requirement is litz wire, probably nine strands for a Q of the order of 100, and twenty or more strands for a Q of 150. Large coil cans are necessary, up to two inches in diameter, with formers of such a size as to make the outside coil diameter little more than half the can diameter. Lastly, self-capacitance must be reduced to a minimum, because its Q is always low and in the case of a single pie winding it may amount to say 25 $\mu\mu$F, a large percentage of the total capacitance. Splitting the winding into pies reduces self-capacitance, at the same time improving the form factor, and a suitable compromise between Q and economy is obtained by winding with three pies. Self-capacitance is also reduced by winding narrow pies, although a limit is set by the difficulty of winding litz wires with a cam of less than 0.1 inch, or perhaps even $\frac{1}{8}$ inch. In addition, as the cam is reduced the height of the coil increases and larger losses from damping of the coil by the can may more than offset the reduced losses in a smaller self-capacitance.

When the windings have more than one pie, the inductance is dependent on pie spacing. For this reason, and to increase the speed of winding, multi-section coils are wound with the former located by a gate, a different slot in the gate being used for each individual pie. Spacing between primary and secondary windings is kept constant by means of a double winding finger which winds primary and secondary at the same time.

After 8 hours or so of work, I've made some changes and did the extra coil tests again. As mentioned above 7.4cm of lead-out wire was removed from the top end of the coil. Beer can distance from extra coil is increased to 28cm. Extra coil raised to 52cm above ground plane. Additional 2.5pF capacitance measured.

Dr. Green #396 (I)

Consideration of Coil Self Capacitance
1) Extra Coil Diameter
8.25 cm

2) Capacitance factor from Radiotron table for a coil aspect ratio of 100%
.46 Numeric

3) Multiply this by the coil diameter
3.8 picofarads

4) This is the "free space" self capacitance of this extra coil. This means a true air wound coil.

Now to determine the actual working capacitance of this extra coil resulting from the coil form and stray lead parasitic capacitance.

1) The theoretical velocity factor from the Wireless Power Table for a coil with a 100% aspect ratio:
187% numeric

2) The actual measured velocity factor
124% numeric

3) Taking the ratio of the free space to actual measured velocity gives
1.51 numeric

Note, close to 1.54, pi/2

4) Velocity varies as the inverse of the square root of the capacitance
2.28 numeric

5) Multiplication of the free space capacitance by this squared factor
8.7 picofarads

6) This is the burdened coil capacitance resulting from the coil form and connecting leads.

Observe that the 45 degree knee or asymptote point is this derived value of capacitance. This effective coil capacitance is the square root of its self capacitance, C and its mutual elastance, K.

Dr Green #396 (II)

Considerations of the magnification factor as derived from the bandwidth of the resonance curve, this the half power, or 71% voltage points on the curve.

1) Determine the 71% points on the extra coil curve (for 10 pFd).

Lower Sideband Point
2821 Kilocycles/sec

Upper Sideband Point
2831 Kilocycles/sec

Hence the half power bandpass is 17 Kilocycles or 6%

2) Two factors are here derived. Factor d is the ratio of the bandwidth to the center frequency, 2830 Kc/sec.
0.006

Factor n is the inverse of factor d:
167

3) Here derived is the magnification factor of this extra coil,
n = 167 numeric

General Conclusions

This extra coil is now quantified as to its general electrical behavior:

v = 124% luminal velocity

C = 8.7 pico
Farad
n = x 167 magnification factor

Dr Green Extra Coil

The inductance, characteristic impedance and resonant frequency of this extra coil is now developed.

1) The magnetic inductance of the extra coil by Wheeler's formula (Theory of Wireless Power) is 846 microHenry

2) The effective inductance for a cosine quarter wavelength current distribution is

by Steinmetz, two over Pi the total inductance,
539 microHenry

By Miller, one half the total inductance,
423 microHenry

3) The equivalent capacitance of the extra coil is given as
8.7 picoFarad

4) The effective capacitance for a sine quarter wave distribution is

by Steinmetz, two over Pi times C,
5.5 picoFarads

by Miller, eight over Pi squared times C,
7.1 picoFarads

4)The Characteristic coil impedance is defined as the square root of the ratio of inductance to capacitance

By Steinmetz

9.9 Kilo Ohm

by Miller
7.7 Kilo Ohm

5) The angular frequency is defined as the inverse of the square root of the product of inductance and capacitance

18 Kilo-radians per second
or
2860 Kilocycles/sec

This concludes the calculation of the important characteristics of the extra coil under study

Nhopa #704 (I)

Basic Secondary Coil Characteristics:

1) From Table 2 of the Theory of Wireless Power, for an aspect ratio of 10 percent, the free space coil velocity effective is
78%

2) The actual frequency is given as
1188 Kilocycles/sec

The luminal frequency is derived as
1856 Kilocycles/sec

And hence the actual velocity effective is given
64% luminal velocity

Note, 63.7% is one over the value of Pi over two

3) From table 1 of the Theory of Wireless Power for a 62 cm diameter coil is given as
60 picoFarads

This is the free space capacitance of the coil.

The actual capacitance is derived from the square of the ratio of free space to actual velocities of this secondary coil.

Ratio of Velocities
126%

Squared giving
1.58 numeric

Capacitance, actual
95 picoFarads

4) Tabulating this data

Luminal velocity
100%

Free space velocity
78%

Actual Velocity
64%

Free Space Capacitance
60 picoFarads

Actual Capacitance 95 picoFarads

Conclusion, coil form and stray lead capacitance add 35 picoFarad of capacitance burden.

Nhopa #704 (II)

The natural, or characteristic impedance, of this secondary coil as a transmission network is derived.

1) By Wheelers formula in the Theory of Wireless Power the total magnetic inductance is given as
444 microHenries

The actual capacitance been given as
95 picoFarads

2) Determining the effective values of inductance and capacitance resulting from the Cosine and Sine quarter wave space distributions the following are derived

By Steinmetz method it is, the effective inductance
283 microHenry

The effective capacitance
60.5 picoFarad

And the effective values from the Miller method it is, the effective inductance
222 microHenry

The effective capacitance
77.1 picoFarad

3) The natural impedance is defined as the square root of the ratio of the inductance to the capacitance, giving

Steinmetz, 2200 Ohm

Miller, 1700 Ohm

4) Hence the primary transmission factors are determined for the secondary coil

v, propagation constant
64%

Z, the natural impedance
1700, or 2200 Ohm
1950 Ohm averaged

Nhopa #704 (III)

It seems that your test coil is too close to secondary, back it away instead of using a ballast resistor. Then look for distance to give the sharpest curve. The magnification factor is the inverse of the bandwidth between the 70.7% down points on each side of the curve.

ALSO NOTE EVERYONE!

I cannot see attachments in coffee shop, I cannot! Post full size pictures then I can respond. Remember also that this provides visual entertainment to the person who is working his/her computer. Remember the coffee shop customer is often a cowboy, or a foreign hiker from France or Italy, they think a Volt is a car by Chevy.

Finally from the Geometric Algebra, Dr Green, and Nhopa material the secondary and extra coils are quantified. It now is a simple matter for any competent person to design a coil for any desired frequency. It is now engineer-able.

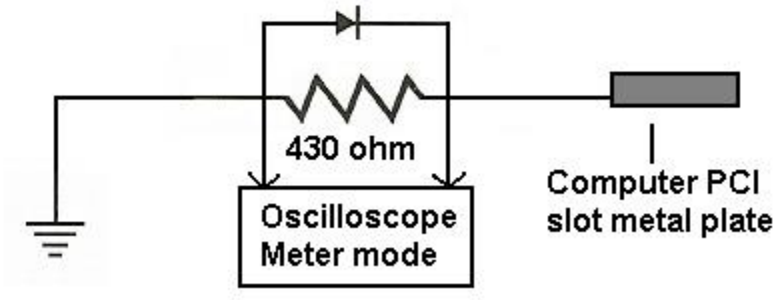
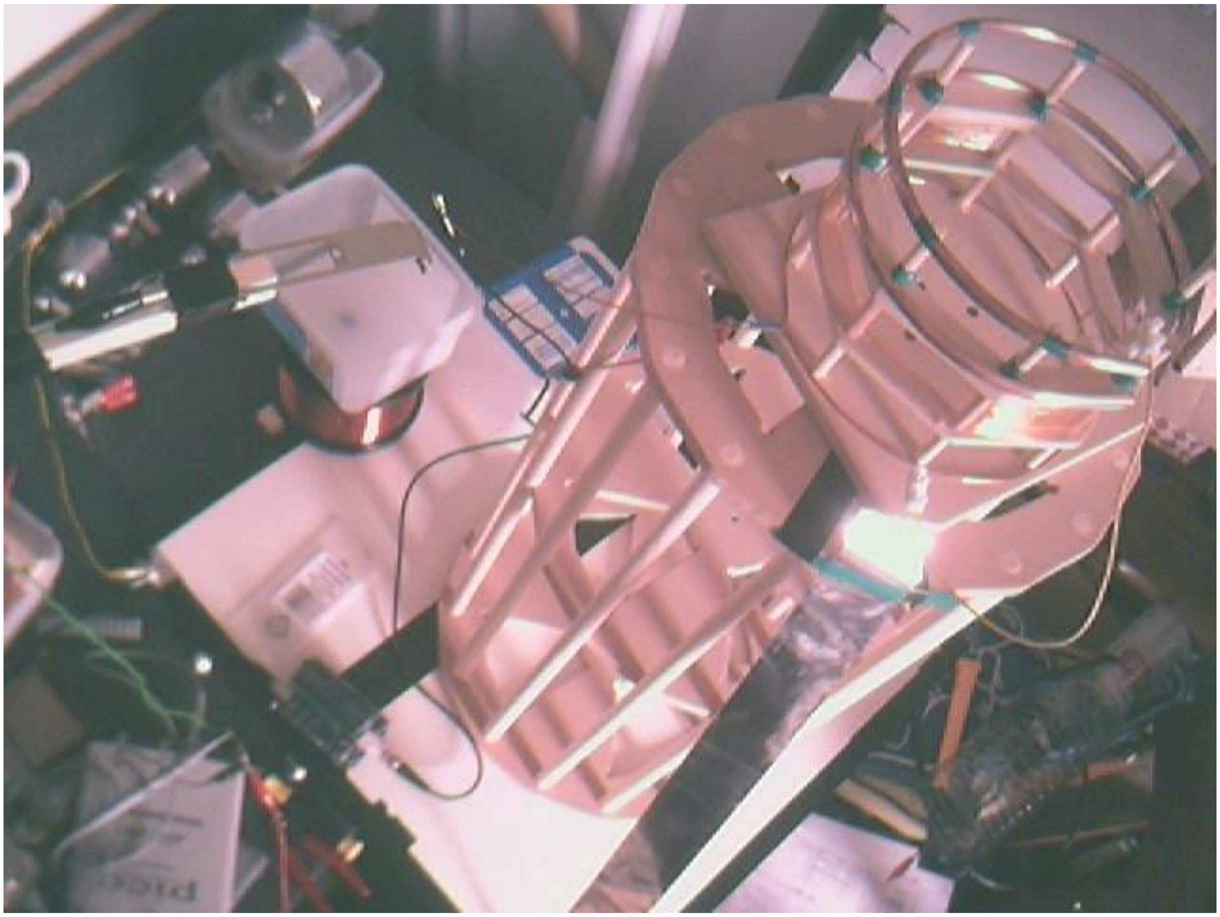
Thank you Eric. I've just completed all the necessary secondary tests, the best I'll be able to do without rewinding it with thicker wire, and/or making a new frame. The preferred plan in that case is to make a bigger coil.

I'm now using a different measuring method so I can see the readings and change the frequency on the computer without getting close and affecting things:



As arranged



The frequency response graphs should now be within 0.3mV accuracy at each sample point and the written peak frequency values within 300 cycles/sec accuracy.

Used the condenser rings as suggested - upper ring connected to secondary neutral. The frame is only just big enough to set the rings at the correct distance. I think ideally the frame should be a little bigger.

The "final" results are as follows:

Secondary without condenser rings peak: 4126 kc
Secondary with condenser rings peak: 3670 kc
Extra Coil with 10pF peak: 2833.1 kc
Extra Coil with metallic connection peak: 2694.8 kc

Extra Coil Calculations and Experiments

1) Tesla, Colorado Springs Notes. Final Extra Coil is found on page 318;
Diameter, 8.4 feet
Length, 8.0 feet
Number of turns, 100 numeric

Now, convert this to meters;
Diameter, 2.55 meter
Length, 2.42 meter

To find the total wire length, mean length of turn multiplied by number of turns;
Coil Circumference, 8.0 meter
Total Wire Length, 800 meter

This establishes the luminal quarter wavelength. The whole wave is hence:
Lambda equals 3200 meters

Dividing this into the velocity of light in meters per second gives
94 Kilocycles per second

This result is the luminal resonant frequency of an equivalent TEM line. We will call this frequency 100 percent luminal velocity.

2) Tesla, Colorado SPrings Notes, page 357, Extra Coil Grounded at neutral end, lamp as capacity terminal. Frequency of resonance is given as:
93.7 Kilocycles/sec
Near 100 percent luminal

3) Tesla, Colorado Springs Notes, page 363, extra coil free with a 38cm end capacitance. The resonant frequency is given as
116.3 Kilocycles/sec
near 124% Luminal

4) Here given by Tesla for the least coupling to the extra coil is 124% luminal velocity. For a "square" coil the free space velocity is 187% the velocity of light. The measured reduction, or retardation, is a result of the dielectric material which supports the coiled windings. The value 124% is seen to agree here in the experiments given by:
1) Geometric Algebra
2) Dr. Green
3) Nhopa
4) Nikola Tesla

All have been burdened to the same extent by dielectric influence and stray lead capacitance.

The challenge here, as was faced by Tesla, is how to make this "self-capacitance" even smaller. Every connecting lead and nearby insulator burdens the coil. The coil form itself is the principle culprit. Is it possible to free the coil to 157%? I did it once with a "PIDUX"air wound coil held together with 6 plastic rods, no more. In conclusion we have now an experimentally verified propagation constant of 124%, the rest is engineering.

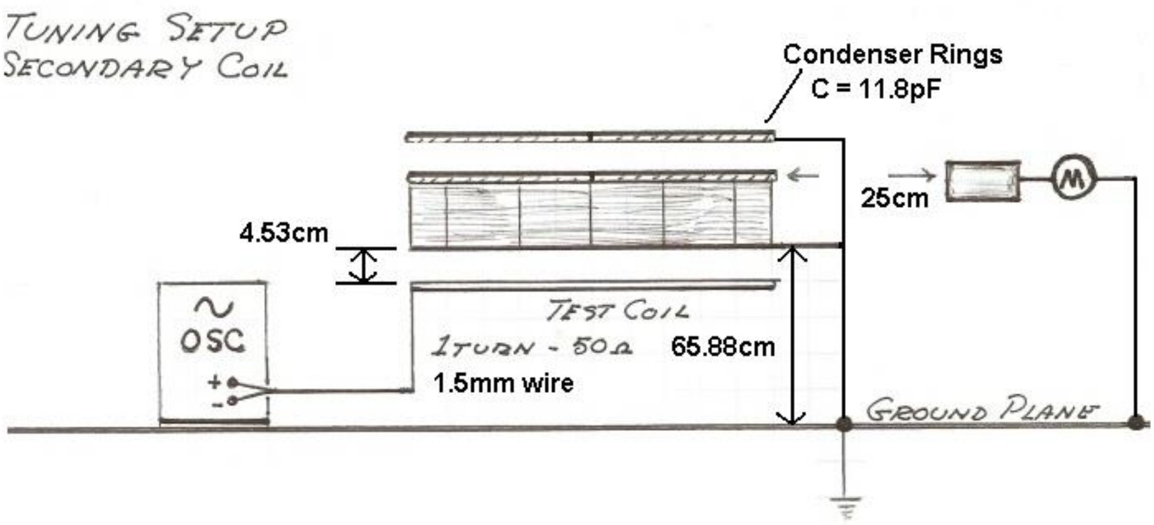
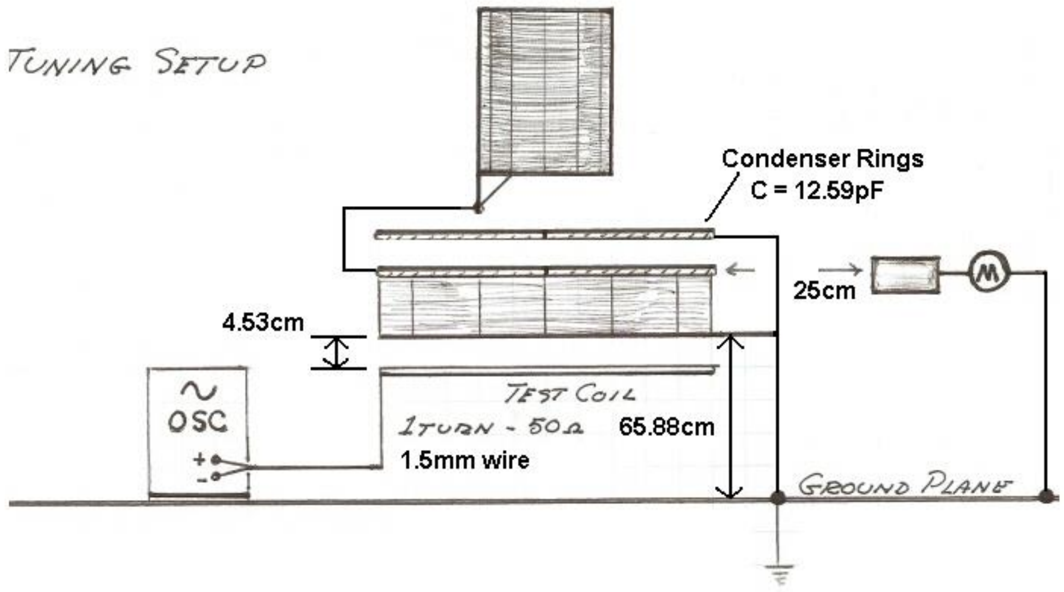
This was the setup in the previous test, condenser rings capacitance measured at 11.8pF to tune the secondary to 3670 kc.



TUNING SETUP
SECONDARY COIL
Condenser Rings
C = 11.8pF
25cm
M
4.53cm
OSC
+
-
TEST COIL
1TURN - 50Ω
65.88cm
1.5mm wire
GROUND PLANE

With the extra coil, the required capacitance is measured at 12.59pF. Set up as so:



TUNING SETUP
Condenser Rings
C = 12.59pF
25cm
4.53cm
OSC
+
-
TEST COIL
1TURN - 50Ω
65.88cm
1.5mm wire
M
GROUND PLANE

Two resonant peaks found with the rings set at 12.59pF, 3670 kc reading 22.7mV, and 2344.2 kc reading 41.3mV.

(The previously mentioned "unreliable" test with the AV plug seemed to show the opposite in terms of light output vs measured voltage).

Assuming I calculated it right, taking 70.7% from post #706:

Magnification Factor @ 3670 kc = 90.20524
Magnification Factor @ 2344.2 kc = 110.44

3670 / 2344.2 = 1.565566

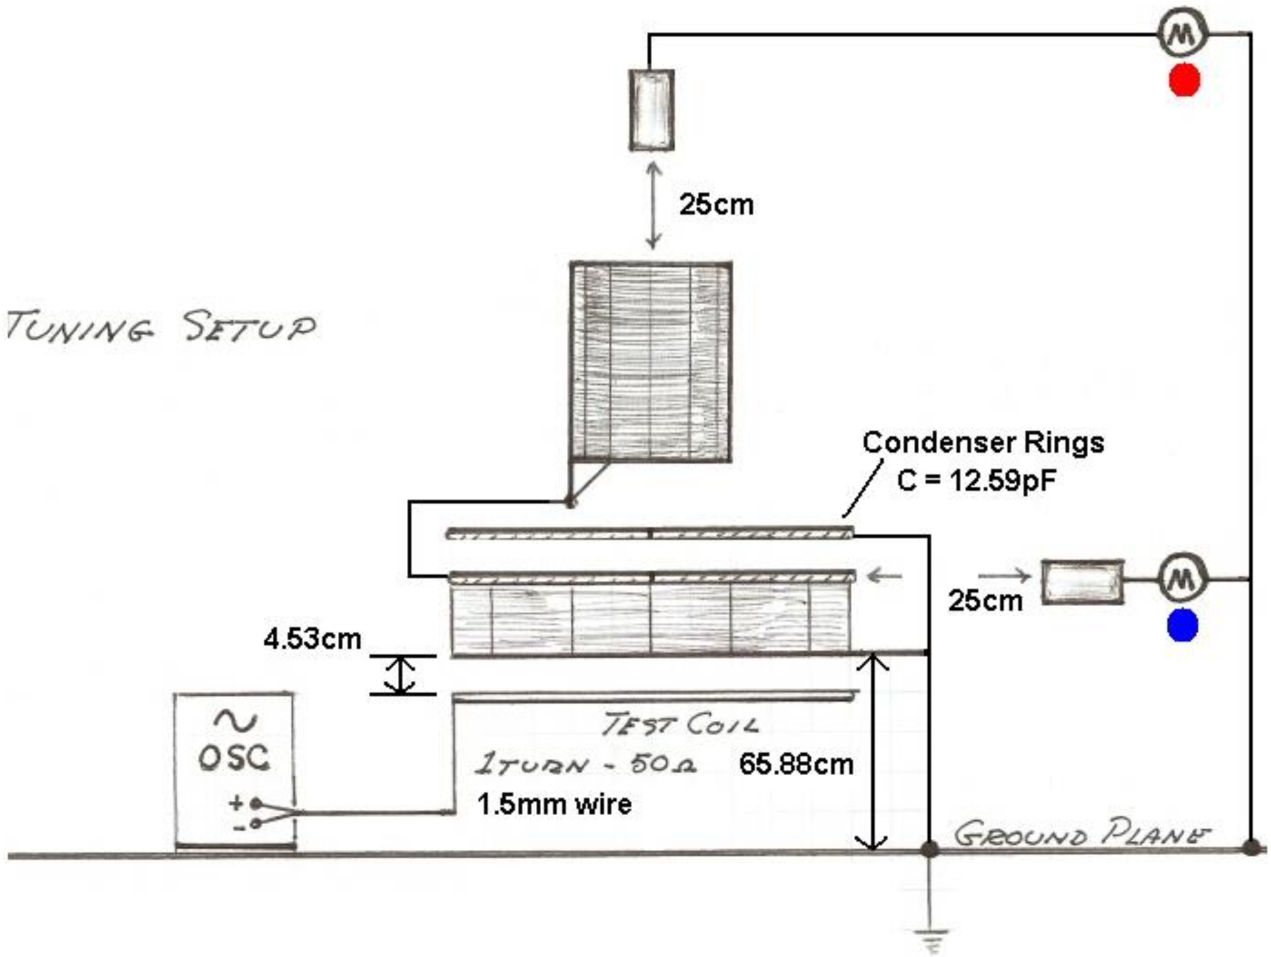
I wasn't happy with the consistency after leaving things overnight and moving the "probes" around and getting rulers in there to measure things etc, so I reset the whole thing and did the secondary test again and extra coil simultaneously. This is now the setup:



TUNING SETUP
M
25cm
Condenser Rings
C = 12.59pF
M
25cm
4.53cm
OSC
+
-
TEST COIL
1TURN - 50Ω
1.5mm wire
65.88cm
GROUND PLANE

Data based on most recent results:

Extra Coil:
126 turns
Diameter = 8.28cm
Height = 8.28cm
Conductor length = 32.271 metres

Luminal frequency = 2322.4 kc
Direct = 2694.8 kc - Magnification Factor = 57.07992
10pF = 2833.1 kc - Magnification Factor = 81.5891

Secondary Coil:
20 turns
Diameter = 20.7cm
Height = 4.08cm
Conductor length = 13.079 metres calculated (approx 12.92 metres used)

Luminal frequency = 5730.4 kc calculated (5800.9 kc for 12.92m)
Free maximum frequency = 4126 kc - Magnification Factor = 63.70233
Rings = 3670 kc - Magnification Factor = 83.71159

Concatenated Coils:
First Peak Resonance: 3670 kc
Second Peak Resonance: 2340 kc

Ratio = 1.568376

Even closer to Pi over two.

So far I've borrowed the inductor (1 metre of wire) with ferrite rod from a basic crystal radio kit. I'm unable to get anything to happen with an incandescent or the fluorescents I have. Incandescents tested were a 3V torch bulb and a Mini Maglite AA bulb both measuring 0.8-1 ohm, fluorescent was a dismantled CFL, 4W and 6W tubes. I might need to make a simple (transistor) amplifier out of parts I have around to get a bit more power than the signal generator can provide.

Dr. Green Coils

The secondary winding is the prime mover of this transformer. Here the system operating frequency is established , and then locked in place by a primary resonator. This in itself establishes a telluric transmission network, a basic resonant transformer with a mono-polar connection at the secondary neutral. Another transformer can be constructed, identical in every way except wound in an opposite direction to the first coil. Interlinking the neutrals of these two counter-wound transformers enables a one wire transmission between the two units. This is the basic telluric system. No more is needed than this.

The extra coil is employed in order to magnify the potential to much higher values than possible with only a secondary winding*. This however involves ratios of refractions and reflection that are difficult to calculate or even understand. Hence its complications are best avoided in basic telluric resting.

*This will increase receiving sensitivity, or "gain"

Two modes are possible for extra coil in relation with the secondary coil. Both involve quarter wave resonant rise, this the fundamental of resonant transformation. Its also known as constant potential to constant current transformation. A constant potential is a zero impedance (short circuit) a constant current is a zero admittance (open circuit). Departure from these zero values alters the coil distribution to something other than a quarter wave.

This quarter wave can exist in a distinct pair of manifestations. The first mode is when the quarter wave is distributed over the length of both extra and secondary windings as a whole, a pair of eighth waves let us say. This is the TANDEM mode. A multiplication in potential is derived hereby since the extra coil exhibits a higher transmission impedance thereby giving rise to a greater EMF between turns and thus a higher termination potential. All photos of my Bolinas and Integratron setups operated in this mode. It is the easy one to achieve.

The second mode of the extra coil and secondary coil connection involves two quarter wave distributions, one on each coil. This is not to be considered a half wave however. This mode is the <b>CONCATENATED</> connection.It compounds the quarter wave resonant rise of the secondary coil with another quarter wave rise in the extra coil, hence a concatenated resonant rise. This is the holy grail of resonant transformer design and unheard of potentials may be gained in this manner. To derive this analytically is extremely difficult, it is an advance transmission line problem. It might not even be possible to calculate or even achieve this mode of resonance, but we are going to give it a try. Tesla dreamed of this mode but electrical knowledge was in its infancy in Tesla's Colorado years. Also note that D. Dawson has become a zealot in drawing us back into the tandem mode of operation, which he claims to have mastered. It has come to pass that he is now becoming a detractor, his denouncements abound. I hereby ignore his posts and caution others that a confusion may develop here for the beginner in this un-charted territory.

In reviewing the Dr. Green material it can be seen that this extra coil is too large, or the wire is too long. Its resonant frequency, even with the lightest coupling, is far below that of the standardizing secondary frequency.

Extra Coil Direct: 2695 Kc/sec
Secondary, rings: 3670 Kc/sec
Frequency ratio: 72% lower
Wavelength ratio: 136% longer

Here seen is that a smaller coil is needed. However to start with, turns can be removed from the existing extra coil. But this shortens the coil, counteracting the turn removal by lowering the velocity and hence lengthening the wavelength of the coil. As a side note, both the secondary and existing extra coil should be tested independently over a wide frequency range to determine if other modes exist. All odd harmonics are resonant modes. Using the information gained from the design and construction of the existing extra coil it is possible to design and construct one for 3670 Kc/sec.

Constructing a pair of counter wound magnification transformers and connecting their neutrals can help minimize the burden of transmission to earth, a significant distorting influence. When possible this should be done. It must be remembered that this effort is really for the experienced transmission engineer, not the HAM operator, and surely not for the beginner. But Tesla was a beginner also, and through systematic experimentation made great progress with what little knowledge of standing and travelling waves in compound circuits that existed in his day. And of course he got no assistance from the pedants like Pupin. Just for fun take this problem of resonance to your local university E.E. professor, but make sure he does not see your license plate number. Is not this the way of modern society, the ones who are supposed to help are useless at best and hostile at worst? Then we have the shills?

I don't know, but there are certainly two modes of operation that seem to be very different. The easiest way to get the 3670 kc resonance is to set the condenser rings to maximum capacitance, with some additional extra coil terminal capacitance. The size of the required terminal increases rapidly as the condenser rings capacity is decreased. In my opinion there is a balance to be found somewhere between the proper resonance of the secondary with the condenser rings and the extra coil with its terminal capacitance.

New extra coil:

Diameter = 8.28cm
Height = 8.28cm
64.25 Turns
Wire length = 16.47 metres 20 SWG (0.9mm)
Luminal frequency = 4550.8 kc
Free space frequency = 8509.996 kc

Terminal capacitance = connected via approx 36cm 14 SWG earth wire, 15cm diameter ball + apple pie tin resting on top + 2 tinfoil "leaves" for fine tuning

Secondary Coil:
20 turns
Diameter = 20.7cm
Height = 4.08cm
Conductor length = 13.079 metres calculated (approx 12.92 metres used)

Luminal frequency = 5730.4 kc calculated (5800.9 kc for 12.92m)
Free maximum frequency = 4126 kc - Magnification Factor = 63.70233
Rings (11.8pF) = 3670 kc - Magnification Factor = 83.71159

Concatenated Coils:
First Peak Resonance: 3670 kc
Second Peak Resonance: 1838 kc

Ratio = 1.996735582

First Peak Resonance Magnification Factor:
Extra coil = 108.2117057
Secondary = Unmeasurable

Second Peak Resonance Magnification Factor:
Extra coil = 88.59539188
Secondary = 102.0317531

Rings capacitance = 29.13pF

Tentative Experimental Circuits, Use at your own risk!

Regenerative receiver is a 2C22 triode, and the pulse generator is a 2050 thyratron, and a 5R4GYB dual diode rectifier.

Pulse Generators, etc

(1) The Guillemen line, or network, can be regarded as an elementary electro-static condenser. It has two terminals, and stores electro-static, or dielectric, energy. this in a manner like the basic condenser. There is one important difference however, this "Guillemen Condenser" is a "loaded condenser".

The common condenser discharge is of a hyperbolic nature, this in Nepers per second. This is not a pulse, it is an impulse. The variation of a pulse is indefinite in time or a discontinuous function, not a hyperbolic one. The hyperbolic function is a result of a rate of change of a quantity which at each instant is proportional to the magnitude of the quantity itself. This gives rise to Epsilon, or base e natural logarithms. It is a law of energy and thermodynamics. The pulse, in distinction to the impulse, represents a constant flow of electric energy, hence constant power.

(2) Previously discussed was the loading on antenna and long distance telephone lines. For the most part the networks described were all four terminal structures, with the exception of reactance arms. The output terminals were the distant telephone, or the Aether itself. The Guillemen network is a two terminal structure and cannot be considered a transmission network as normally understood. Now it is a transmission network in a counter spatial form. So as with a loaded electro-magnetic telephone pair, a four terminal network, the Guillemen line is a loaded dielectric network, a two terminal network. In his book "communication networks", volume 2, Guillemen is close to a wave equation for counterspace. The "Type A" line can be considered a longitudinal magneto-dielectric transmission line. This is important.

(3) For pulse experimentation I recommend the 2050 Argon Thyratron, this instead of a 5C22. Likewise, a 5R4G dual half-wave rectifier can replace the pair of 705 H.V. diodes. This is where to start.

The OA4G has application as a radiant matter detector. The main circuit consists of a Western Electric Telephone Bell in series with the plate supply. The bell condenser should be connected in shunt to the bell windings. A contact should be fitted to the bell armature to break the cathode connection to the OA4G in order to reset the tube. See the Marconi Coherer detector.

(4) Th cosmic anode lead connects to the trigger or grid lead of the OA4G. There must be NO DC leakage to ground. For cosmic anodes see Vassilatos "Vril Compendium", and the experiments of Luigi Galvani.

(5) As for detectors into the outer limits the common regenerative detector is the circuit of choice. It is a development of E.H. Armstrong, see "Empire of the Air". The Regenerative

Detector is also developed in the Russian parametric paper, an important study. Radionic receivers here are possible, depending on the metallic-dielectric geometry used. Connection with a magnification transformer is possible.

Finally, the bulbs. The neon sign shops receive their gas in large glass globes. It is at a bit less than atmospheric pressure and when exhausted it of course is at the same pressure as the neon tube under construction. These bulbs then are junk to the neon guy. Great glom potential! These bulbs can be pumped further with a diffusion pump and a small ion gun can be placed in its neck, or a Tesla electrode fitted inside. Many possibilities.

(6) So sell your Bedini junk off on e-bay to the Chinese. Dispense with the Grey tube secrets and the rest of the useless lot. These are only dummy loads to tax your resources and keep your mind chasing its own tail. It is established here that the old "Electrical Experimenter" can come back to life, the possibilities are infinite.

coupling shown in Fig. 5-5. The same order of inductance is required as with the pentode grid-leak detector described previously.

The plate detector is more sensitive than the diode since there is some amplifying action in the tube, but less so than the grid-leak detector. It will handle considerably larger signals than the grid-leak detector, but is not quite so tolerant in this respect as the diode. Linearity, with the self-biased circuits shown, is good. Up to the overload point the detector takes no power from the tuned circuit, and so does not affect its Q and selectivity.

Infinite-Impedance Detector

The circuit of Fig. 5-6 combines the high signal-handling capabilities of the diode detector with low distortion (good linearity), and, like the plate detector, does not load the tuned circuit it connects to. The circuit resembles that of the plate detector, except that the load resistance, R_1, is connected between cathode and ground and thus is common to both grid and plate circuits, giving negative feed-back for the audio frequencies. The cathode resistor is by-passed for r.f. (C_2) but not for audio, while the plate circuit is by-passed to ground for both audio and radio frequencies. R_2 forms, with C_3, an RC filter to isolate the plate from the "B" supply at a.f. An r.f. filter, consisting of a series r.f. choke and a shunt condenser, can be connected between the cathode and C_4 to eliminate any r.f. that might otherwise appear in the output.

The plate current is very low at no signal, increasing with signal as in the case of the plate detector. The voltage drop across R_1 similarly increases with signal, because of the increased plate current. Because of this and the fact that the initial drop across R_1 is large, the grid cannot be driven positive with respect to the cathode by the signal, hence no grid current can be drawn.

REGENERATIVE DETECTORS

By providing controllable r.f. feed-back or regeneration in a triode or pentode detector circuit, the incoming signal can be amplified many times, thereby greatly increasing the sensitivity of the detector. Regeneration also increases the effective Q of the circuit and increases the selectivity because the maximum regenerative amplification takes place only at the frequency to which the circuit is tuned. The grid-leak type of detector is most suitable for the purpose. Except for the regenerative connection, the circuit values are identical with those previously described for this type of detector, and the same considerations apply. The amount of regeneration must be controllable, because maximum regenerative amplification is secured at the critical point where the circuit is just about to oscillate, and the critical point in turn depends upon circuit conditions, which may vary with the frequency to which the detector is tuned. In the oscillating condition, a regenerative detector can be detuned slightly from an incoming c.w. signal to give *autodyne* reception.

Fig. 5-7 shows the circuits of regenerative detectors of various types. The circuit of A is for a triode tube, with a variable by-pass condenser, C_3, in the plate circuit to control regeneration. When the capacity is small the tube does not regenerate, but as it increases toward maximum its reactance becomes smaller until a critical value is reached where there is sufficient feed-back to cause oscillation. If L_2 and L_3 are wound end-to-end in the same direction, the plate connection is to the outside of the plate or "tickler" coil, L_3, when the grid connection is to the outside of L_2.

The circuit of 5-7B is for a pentode tube, regeneration being controlled by adjustment of the screen-grid voltage. The tickler, L_3, is in the plate circuit. The portion of the control resistor between the rotating contact and ground is by-passed by a large condenser (0.5 μfd. or more) to filter out scratching noise when the arm is rotated. The feed-back is adjusted by varying the number of turns on L_3 or the coupling between L_2 and L_3, until the tube just goes into oscillation at a screen potential of approximately 30 volts.

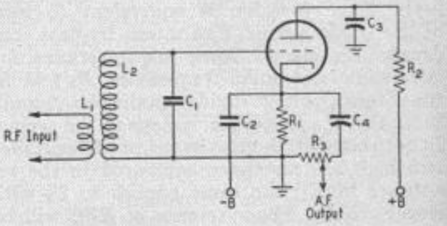

Fig. 5-6 — **The infinite-impedance detector. The input circuit, L_2C_1, is tuned to the signal frequency. Typical values for the other components are:**

C_2 — 250 μμfd. R_1 — 0.15 megohm.
C_3 — 0.5 μfd. R_2 — 25,000 ohms.
C_4 — 0.1 μfd. R_3 — 0.25-megohm volume control.

A tube having a medium amplification factor (about 20) should be used. Plate voltage should be 250 volts.

Circuit C is identical with B in principle of operation, except that the oscillating circuit is of the Hartley type. Since the screen and plate are in parallel for r.f. in this circuit, only a small amount of "tickler" — that is, relatively few turns between the cathode tap and ground — is required for oscillation.

Smooth Regeneration Control

The ideal regeneration control would permit the detector to go into and out of oscillation smoothly, would have no effect on the frequency of oscillation, and would give the same value of regeneration regardless of frequency and the loading on the circuit. In practice, the effects of loading, particularly the loading that occurs when the detector circuit is coupled to an antenna, are difficult to overcome. Likewise, the regeneration is usually affected by the frequency to which the grid circuit is tuned.

In all circuits it is best to wind the tickler at the ground or cathode end of the grid coil, and to use as few turns on the tickler as will allow the detector to oscillate easily over the whole tuning range at the plate (and screen, if a pentode) voltage that gives maximum sensitivity. Should the tube break into oscillation suddenly as the regeneration control is advanced, making a click, the operation often can be made smoother by changing the grid-leak resistance to a higher or lower value. The wrong grid leak plus too-high plate and screen voltage are the most frequent causes of lack of smoothness in going into oscillation.

Antenna Coupling

If the detector is coupled to an antenna, slight changes in the antenna constants (as when the wire swings in a breeze) affect the frequency of the oscillations generated, and thereby the beat frequency when c.w. signals are being received. The tighter the antenna coupling is made, the greater will be the feed-back required or the higher will be the voltage necessary to make the detector oscillate. The antenna coupling should be the maximum that will allow the detector to go into oscillation smoothly with the correct voltages on the tube. If capacity coupling to the grid end of the coil is used, only a very small amount of capacity will be needed to couple to the antenna. Increasing the capacity increases the coupling.

At frequencies where the antenna system is resonant the absorption of energy from the oscillating detector circuit will be greater, with the consequence that more regeneration is needed. In extreme cases it may not be possible to make the detector oscillate with normal voltages, causing so-called "dead spots." The remedy for this is to loosen the antenna coupling to the point that permits normal oscillation and smooth regeneration control.

Body Capacity

A regenerative detector occasionally shows a tendency to change frequency slightly as the hand is moved near the dial. This condition (**body capacity**) can be caused by poor design of the receiver, or by the antenna if the detector is coupled directly to it. If body capacity is present when the antenna is disconnected, it can be eliminated by better shielding, and sometimes by r.f. filtering of the 'phone leads. Body capacity that is present only when the antenna is connected is caused by resonance effects in the antenna, which tend to raise the whole detector circuit above ground potential. A good, short ground connection should be made to the receiver and the length of the antenna varied electrically (by adding a small coil or variable condenser in the antenna lead) until the effect is minimized. Loosening the coupling to the antenna circuit also will help.

Hum

Hum at the power-supply frequency may be present in a regenerative detector, especially when it is used in an oscillating condition for c.w. reception, even though the plate supply itself is free from ripple. The hum may result from the use of a.c. on the tube heater, but effects of this type normally are troublesome

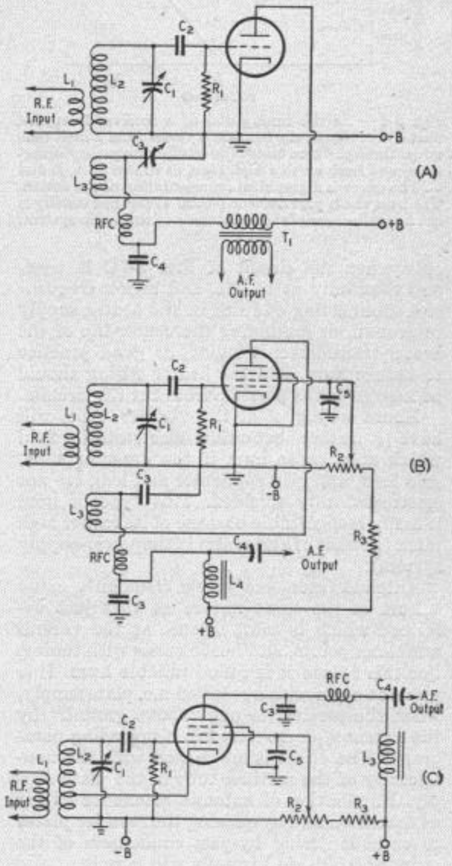

Fig. 5-7 — Triode and pentode regenerative detector circuits. The input circuit, L_2C_1, is tuned to the signal frequency. The grid condenser, C_2, should have a value of about 100 μμfd. in all circuits; the grid leak, R_1, may range in value from 1 to 5 megohms. The tickler coil, L_3, ordinarily will have from 10 to 25 per cent of the number of turns on L_2; in C, the cathode tap is about 10 per cent of the number of turns on L_2 above ground. Regeneration-control condenser C_3 in A should have a maximum capacity of 100 μμfd. or more; by-pass condensers C_3 in B and C are likewise 100 μμfd. C_5 is ordinarily 1 μfd. or more; R_2, a 50,000-ohm potentiometer; R_3, 50,000 to 100,000 ohms. L_4 in B (L_3 in C) is a 500-henry inductance. C_4 is 0.1 μfd. in both circuits. T_1 in A is a conventional audio transformer for coupling from the plate of a tube to a following grid. *RFC* is 2.5 mh. In A, the plate voltage should be about 50 volts for best sensitivity. Pentode circuits require about 30 volts on the screen; plate potential may be 100 to 250 volts.

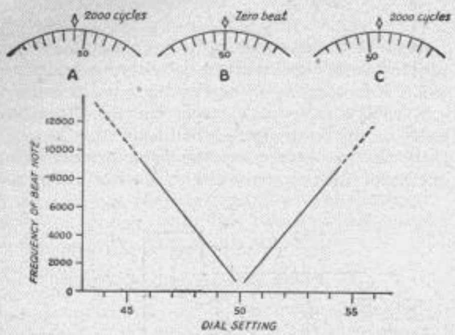

Fig. 5-8 — As the tuning dial of a receiver is turned past a c.w. signal, the beat-note varies from a high tone down through "zero beat" (no audible frequency difference) and back up to a high tone, as shown at A, B and C. The curve is a graphical representation of the action. The beat exists past 8000 or 10,000 cycles but usually is not heard because of the limitations of the audio system.

only when the circuit of Fig. 5-7C is used, and then only at 14 Mc. and higher frequencies. Connecting one side of the heater supply to ground, or grounding the center-tap of the heater-transformer winding, is good practice to reduce hum, and the heater wiring should be kept as far as possible from the r.f. circuits.

House wiring, if of the "open" type, will have a rather extensive electrostatic field which may cause hum if the detector tube, grid lead, and grid condenser and leak are not electrostatically shielded. This type of hum is easily recognizable because of its rather high pitch (a result of harmonics in the power-supply system).

Antenna resonance effects frequently cause a hum of the same nature as that just described which is most intense at the various resonance points, and hence varies with tuning. For this reason it is called **tunable hum.** It is prone to occur with a rectified-a.c. plate supply, when the receiver is put "above ground" by the antenna, as described in a preceding paragraph. The effect is associated with the non-linearity of the rectifier tube in the plate supply. Elimination of antenna resonance effects as described and by-passing the rectifier plates to cathode (using by-pass condensers of the order of 0.001 μfd.) usually will cure it.

Tuning

For c.w. reception, the regeneration control is advanced until the detector breaks into a "hiss," which indicates that the detector is oscillating. Further advancing the regeneration control after the detector starts oscillating will result in a slight decrease in the strength of the hiss, indicating that the sensitivity of the detector is decreasing.

The proper adjustment of the regeneration control for best reception of c.w. signals is where the detector just starts to oscillate, when it will be found that c.w. signals can be tuned in and will give a tone with each signal depending on the setting of the tuning control. As the receiver is tuned through a signal the tone first will be heard as a very high pitch, then will go down through "zero beat" (the region where the frequencies of the incoming signal and the oscillating detector are so nearly alike that the difference or beat is less than the lowest audible tone) and rise again on the other side, finally disappearing at a very high pitch. This behavior is shown in Fig. 5-8. It will be found that a low-pitched beat-note cannot be obtained from a strong signal because the detector **"pulls in"** or **"blocks"**; that is, the signal tends to control the detector in such a way that the latter oscillates at the signal frequency, despite the fact that the circuit may not be tuned exactly to resonance. This phenomenon, commonly observed when an oscillator is coupled to a source of a.c. voltage of approximately the frequency at which the oscillator is operating, is called **"locking-in"**; the more stable of the two frequencies assumes control over the other. "Blocking" usually can be corrected by advancing the regeneration control until the beat-note occurs again. If the regenerative detector is preceded by an r.f. amplifier stage, the blocking can be eliminated by reducing the gain of the r.f. stage. If the detector is coupled to an antenna, the blocking condition can be satisfactorily eliminated by advancing the regeneration control or loosening the antenna coupling.

The point just after the detector starts oscillating is the most sensitive condition for c.w. reception. Further advancing the regeneration control makes the receiver less prone to blocking by strong signals, but also less capable of receiving weak signals.

If the detector is in the oscillating condition and a 'phone signal is tuned in, a steady audible beat-note will result. While it is possible to listen to 'phone if the receiver can be tuned to exact zero beat, it is more satisfactory to reduce the regeneration to the point just before the receiver goes into oscillation. This is also the most sensitive operating point.

Audio-Frequency Amplifiers

The ordinary detector does not produce very much audio-frequency power output — usually not enough to give satisfactory sound volume, even in headphone reception. Consequently, audio-frequency amplifiers are used after the detector to increase the power level. One amplifier usually is sufficient for headphones, but two stages generally are used where the receiver is to operate a loudspeaker. A few milliwatts of a.f. power are sufficient for headphones, but a loudspeaker requires a watt or more for good room volume.

The Superregenerative Receiver

The simplest type of v.h.f. receiver is the superregenerator, for many years the most popular receiver for v.h.f. work. It affords fair sensitivity with few tubes and elementary circuits, and though it has largely been replaced by the more effective superheterodyne for home-station use, it still has many v.h.f. applications. Its disadvantages are lack of selectivity, poor signal-to-noise ratio on weak signals, and its tendency to radiate a strong signal which causes severe interference.

Its selectivity may be improved somewhat and its interference capabilities reduced by the addition of an r.f. stage, a refinement which should be considered a necessity if the receiver is to be used in a locality where there are other stations operating on the same band. If no r.f. stage is used, as in portable applications where economy of space and battery drain are primary considerations, the detector should be operated with the lowest plate voltage that will permit superregeneration, in order to reduce its interference range.

From a practical aspect, superregenerative receivers may be divided into two general types. In the first the quenching voltage is developed by the detector itself, called a "self-quenched" detector. In the second, a separate low-frequency oscillator is used to generate the quench voltage. Self-quenched detectors have found wide favor, particularly for portable work; but it is possible to achieve better performance with the separately-quenched type, particularly as the frequency approaches the upper limit of the tube's capabilities.

Superregeneration Principles

The limit to which ordinary regenerative amplification can be carried is the point at which oscillation commences, since at that point further amplification ceases. The superregenerative detector overcomes this limitation by introducing into the detector circuit an alternating voltage of a frequency somewhat above the audible range, the value being between 20 and 200 kc. depending on the signal frequency. Because the oscillations are constantly being interrupted by this quenching voltage the regeneration can be greatly increased, and the amplified signal will build up to tremendous proportions. A one-tube superregenerative receiver is capable of an inherent sensitivity approaching the thermal-agitation noise level of the tuned circuit, and may have an antenna input sensitivity of two microvolts or better.

Because of its inherent characteristics, the superregenerative circuit is suitable only for the reception of modulated signals, and operates best on the very-high frequencies. Typical superregenerative circuits for separately-quenched and self-quenched detectors are shown in Fig. 12-21, but the basic circuit may be any of the various arrangements used for straight regenerative detectors.

In the self-quenched detector the frequency of the quench oscillation depends upon the feed-back and upon the time constant of the grid leak and condenser, the oscillation being a "blocking" or "squegging" in which the grid accumulates a strong negative charge which does not leak off rapidly enough through the grid leak to prevent a relatively slow variation of the operating point.

The greater the difference between the quenching and signal frequencies the greater the amplification, because the signal then has a longer period in which to build up during the nonquenching half-cycle when the resistance of the circuit is negative. This ratio should not exceed a certain limit, however, for during the quenched or nonregenerative intervals the input selectivity is merely that of the Q of the tuned circuit alone.

Because of the greater amplification, the hiss noise when a super-

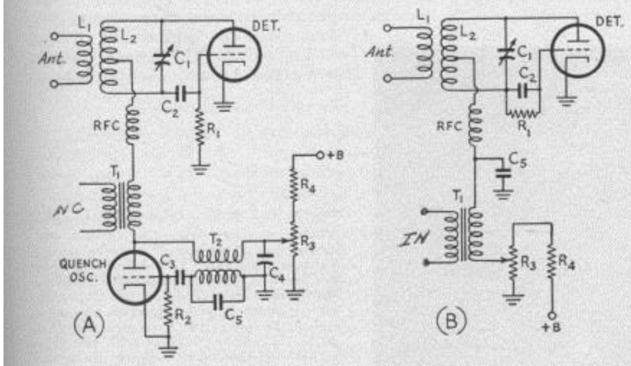

Fig. 12-21 — (A) Superregenerative detector circuit using a separate quench oscillator. (B) Self-quenched superregenerative detector circuit. L_2C_1 is tuned to the signal frequency. Typical values for other components are:

C_2 — 47 μμfd.
C_3 — 470 μμfd.
C_4 — 0.1 μfd.
C_5 — 0.001–0.005 μfd.
R_1 — 2 — 10 megohms.
R_2 — 47,000 ohms.
R_3 — 50,000-ohm potentiometer.
R_4 — 47,000 ohms.
RFC — R.f. choke, value depending upon frequency. Small low-capacitance chokes are required for v.h.f. operation.
T_1 — Audio transformer, plate-to-grid type.
T_2 — Quench-oscillator transformer.

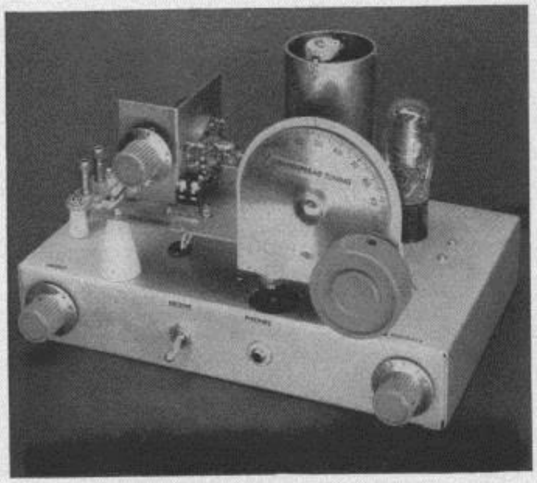

Fig. 12-22 — Front view of the coaxial-line receiver. The r.f. amplifier tuning control is at the left and the main control, for the concentric-line detector circuit, is at the right side of the unit. The audio gain control, send-receive switch, 'phone jack and regeneration control can be seen in that order, from left to right, across the front wall of the chassis.

regenerative detector goes into oscillation is much stronger than with the ordinary regenerative detector. The most sensitive condition is at the point where the hiss first becomes marked. When a signal is tuned in, the hiss will disappear to a degree that depends upon the signal strength.

Lack of hiss indicates insufficient feed-back at the signal frequency, or inadequate quench voltage. Antenna-loading effects will cause dead spots that are similar to those in regenerative detectors and can be overcome by the same methods. The self-quenching detector may require critical adjustment of the grid-leak and grid-condenser values for smooth operation, since these determine the frequency and amplitude of the quench voltage.

● A COAXIAL-LINE SUPERREGENERATIVE RECEIVER FOR 220 MC.

The performance of a superregenerative receiver, both as to selectivity and smoothness of operation, can be improved by the use of a coaxial line tank in the grid circuit of the detector, in place of the customary coil and condenser. Addition of an r.f. amplifier stage will improve sensitivity, reduce radiation, and make antenna coupling less critical. A superregenerative receiver for 220 to 240 Mc. incorporating these features is shown in Figs. 12-22–12-25.

The r.f. tube is a 954 acorn with a conventional tuned circuit in its grid. The plate circuit is a self-resonant loop, which is coupled to the concentric line grid circuit of the 6AK5 detector. The detector output is fed through a quench filter to a

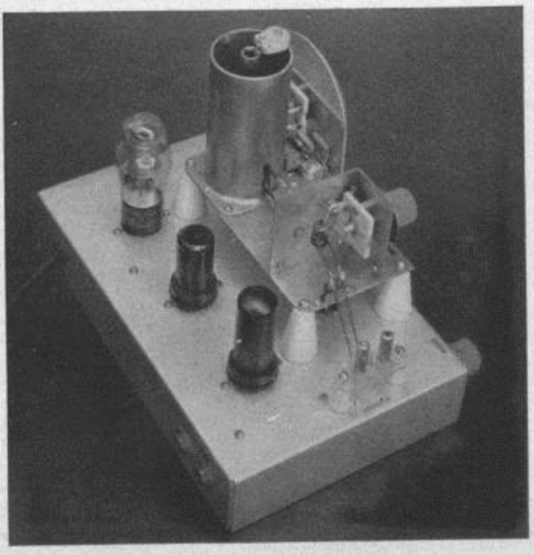

Fig. 12-23 — Rear view of the superregenerative receiver. The r.f. circuits are mounted on a copper shelf to the left of the antenna terminals. The detector tuning condenser is mounted on a small panel to the front of the coaxial line, and the bandset condenser is soldered across the open end of the line. The r.f. stage is mounted on an "L"-shaped bracket with the tube socket and plate-circuit components on the left side and the grid circuit on the right side. Audio tubes and voltage regulator are in line across the rear of the chassis.

Notes on Tesla Transceiving 2

You are all playing with my first fully mathematical design, no books, no experiment, just a pad of paper in the seat of my Corolla sitting in between giant rocks, one 14,500 feet high! And you all have shown it to work. It must be noted here the given extra coil is a compromise, Colorado Unit will not completely scale down to broadcast band without excessive turns of fine wire on a tiny extra coil.

Note that a primary condenser is a must and it must match the KVar of the primary coil. Equal surfaces or equal weight for coil and condenser, a good "Rule of Thumb". There must be no breaks, gaps, etc between the coil and condenser, NONE! Tesla says this in his refined designs. (Fig 1)

The final setup at Colorado Springs, the FINAL ONE, should go on forum;

1) Coil heights, widths,
2) Number of turns,
3) Wire Gauge, and number of wires in primary bundle,
4) Length of wire in secondary and extra coils,
5) Operating frequencies,
6) Primary condenser connections and auxilliary devices in with the primary system

This is of extreme importance, do not get hung up on test coils, un-related experiments, or early transformer construction, we want ONLY his finished product known to be his final perfection for earth resonance. Can anyone do this and not put out distractive parts of Tesla's notebook? Let us see. Also a compendium of everyone's unit is important here.

In conclusion I am very happy to see how all this grew out of a few pages of equations scribbled in the front seat of my Corolla to an International Experimental Effort. From my first efforts in 1980 at RCA to a final design equation in 2012. It was long path to follow.

Soon my name in this will be forgotten by everyone and some will claim it their own idea, then I can join Tesla in oblivion. As Peter Lindemann expressed when asked about the widespread use of my material without my knowledge or consent, that Eric is just an A-hole so no one wants to involve him in his own discoveries. My multi-wave oscillator antenna is in wide use through Lindemann, Borderland, etc and I get nothing. Well it is just a small bit of the over 50 Kilobux Borderland embezzled from me. Tom Brown told me that I owed it to (Her), that, (She), needed it more than I did. Well (She) is dead now and the money is spent. The notes, record, equipment of my work is long gone, good buddy Tom Brown. It serves Al-Gora well that all the records of my RCA solar-terrestrial work vanished, so who is helping who?

When I undertook providing this forum with the means of duplicating a part of Tesla's work, this in the form of the C.R.I., it was tacitly assumed that it would be used responsibly, no weapon development, no interference to other services, only legal and responsible use. This requirement has been violated. Moreover flouted attitudes of punk personalities serve to negate my own interest in making my efforts known to this forum, or anyone at all. It in no way serves my own interest to provide any info here, and I am in fact serving as a prostitute on this forum, spreading my legs for a few sheckels to keep the car running. You can rest assured once a coyote is not pinned down it will just vanish into invisibility.

73-DE-N6KPH

Note Jake,
1) This is the starting point of the "World System" (on 400 Kc!), a "Ham radio" net.
2) A.M. stations are pilot signals for the experimenter, this makes it easy and legal to work with Tesla Systems, a receive only development.

Engineering analysis of the Colorado Springs Tesla Magnifying Transformer

Preface: the following material and calculations are taken from the Tesla Colorado Springs Notebook. An index of important pages is given at the end.

1) The Colorado Transformer consists in part of a basic quarter wave resonant transformer, referred to in the notes as the primary-secondary structure. The primary circuit is of the balanced, open loop break, configuration. This break in the primary loop gives rise to steep transient waves. This in turn gives rise to a multitude of harmonic travelling waves upon the coiled windings which constitute the Tesla Transformer. This is discussed in “Condensed Intro to Tesla Transformers.” Like did Tesla, we will focus on the sinusoidal, single frequency, distributions.

2) Next is the extra coil. This coil here operates with a propagation constant less than an eighth of a wavelength. Therefore the coil is operating as a simple inductance coil, not as a distributed network. The distributed network capacity of this mode can be expressed as a definite terminal capacitance. Hence the inductance of this coil is adequately represented by its static inductance.

3) Finally is the capacity mast. The effective electrostatic capacity of this mast is given. To convert from C.G.S. “centimeters” first divide by the speed of light squared, in centimeters per second, then multiply by ten to the plus ninth. This gives Farads. It works out to 1.1 times C.G.S. gives picoFarads. How easy.

The capacity of the mast consists of two components, one is the self capacity to earth in per Farads, the other is the mutual elastivity K to the ionosphere in per Farads. The measured mast capacity is a resultant, the square root of the ratio of self capacity, C, to the mutual elastivity, K. The actual values of C and K are unknown. The square root of the product of C and K is the propagation constant. The smaller the value of this constant, the greater is the electro-static coupling to the ionosphere.

4) It should be noted that the earth connection at this location was very poor. It was not adequate for the system neutrals. This gives rise to stray mutual inductance between neutral connections. This also led to travelling waves on the two wire 1000 volt power line that powered the Tesla system. Standing waves in the distant generator windings shorted out these coils burning out the town’s generator station.

In conclusion, the Colorado Tesla Transformer is most basic. An extremely high electromotive force is established through the employment of a large lumped series resonant circuit. This series circuit consists of a static inductance coil, the extra coil, and a static capacitance, the capacity mast. This is a basic LC circuit.

This LC circuit is fed by a constant current resonant transformer as a source of low frequency alternating current energy. The operating frequency is near 45 Kilocycles.

5) The propagation constants and the transmission impedances can be derived from the basic physical dimensions of this system. It is fortunate that we have the “RadioTron Designers Handbook”, Tesla did not. He had no frequency counter, no scope, no W.W.V. time standard, Nothing! Think about this.

6) **SECONDARY COIL DIMENSIONS AND CONSTANTS**

Diameter: 15 meters
Height: 1 meter
Number of Turns: 17 numeric
Mean Length of Turn: 47 meters
Total Length of Turns: 800 meters
Luminal Wavelength: 3200 meters
Self Capacitance: 1500 picoFarad
Self Inductance: 10 milliHenry
Luminal Frequency: 94 Kc/sec
Free Space Frequency: 64 Kc/sec
Actual Frequency: 43 Kc/sec
Free Space Propagation: 68%
Actual Propagation: 46%
Transmission Impedance: 2500 Ohm
Dielectric Burden: 330 picoFarads

7) **EXTRA COIL DIMENSIONS AND CONSTANTS**

Diameter: 8.4 feet
Height: 8.0 feet
Number of Turns: 100 numeric
Mean Length of Turn: 8 meters
Total Length of Turns: 800 meters
Luminal Wavelength: 3200 meters
Self Capacitance: 112 picoFarad
Self Inductance: 25 milliHenry
Luminal Frequency: 94 Kc/sec
Free Space Frequency: 176 Kc/sec
Actual Frequency: 116 Kc/sec
Free Space Propagation: 187%
Actual Propagation: 123%
Transmission Impedance: 15 Kilo-Ohm
Dielectric Burden: 26 picoFarads

8) **MAST CAPACITANCE EFFECTIVE VALUE:**

Measured Capacitance is given approximately at 320 picoFarads

The self capacitance of the extra coil is given as 112 picoFarad.

The total capacitance is hence given,
Total End Capacity, 432 picoFarad

This end capacity is series resonant with a 25 milliHenry inductance coil. This gives rise to a propagation constant, (the resonant frequency) and to a transfer impedance.

9) The propagation constant, or frequency, is defined as the inverse of the quantity consisting of the square root of the inductance times the capacitance, this root then multiplied by two Pi. Hence cycles per second.

The product,
25 milliHenry times 432 picoFarad
Results in a frequency of
47 Kilo-cycles

10) The transfer impedance is given as the square root of the ratio of the inductance to the capacitance.

25 milliHenry divided by 432 picoFarad
Results in an impedance of
7600 Ohm

This represents the output impedance of the Tesla Magnifying Transformer.

In basic terms, a 45 Kc/sec 2500 Ohm source of alternating current energy energizes a large series resonant circuit consisting of an inductance coil and elevated capacity structure. At 45 Kilo-cycles per second, every ampere supplied to the extra coil gives rise to 7.6 Kilovolts at the elevated capacity terminal. The effects of higher harmonics and distributed constants can raise this potential by no more than 50% over the base 7.5 KV. Hereby, for a capacity potential of 1000 KV, the input current to the extra coil must be 132 amperes at 45 Kilocycles per second.

12) This derives the total KiloVolt-Ampere reactive activity of the extra coil in 1000 KV operation, hence, the total activity;

132 MegaVolt-Ampere

This is a substantial activity of 174 thousand horsepower, remembering that this is an average value, the peak value is unknown.

13) In conclusion, the Colorado Springs Tesla Magnification Transformer is a very simple system, no more than a giant series resonant circuit with an approximately sinusoidal waveform rendered asymmetrical by a moderate dampening constant. The extra coil is not operating as a transmission network of distributed constants, but only as a basic inductance coil. Hence the length of wire on the coil is somewhat **immaterial.** The mast capacitance swamps out the extra coil self capacitance, this suppressing transmission modes of higher harmonics.

This transformer is seen to be somewhat disappointing to the theorist. No fancy travelling wave interaction nor any stupendous harmonic conjunctions, only a **Big Series Resonant Circuit.** It can be surmised that the Colorado Springs Transformer was incapable of full mono-polar operation, due to the suppression of distributed constants. What is fortunate is that with the material hereby provided the Colorado Springs Tesla Transformer can be scaled down to any convenient size for experimentation. This setup is now quantified, and the mystics can remain silent.

Resonant Magnification

Today we have the good fortune of the permission to experiment in the transformer yard of a department of water and power generating station. The station station is down for maintenance and one bank of line transformers is available for our experiments. This bank has a wye connected secondary of 60 Kilo-Volt line to neutral voltage. The primary windings are in a delta connected 2.4 KiloVolt line to line voltage, these to the generators.

Now one transformer is removed from the bank, its 2.4 Kilo-Volt primary will remain unused. The secondary coil is asymmetrical for grounded neutral connection. Hence the secondary coil has a high voltage bushing for line connection, and a distribution voltage bushing for neutral connection. See Figure (1). This is an "odd order series" winding, or a "quarter wave" type configuration.

This single phase power transformer has the following specifications:
Full Load Capacity: 3000 KiloVolt - Amperes
Secondary Voltage: 60 KiloVolts
Basic Impulse Level: 300 KiloVolts

Measurements on the secondary windings give the following results:
D.C. Winding Resistance: 24 Ohms
60 cycle Winding Reactance: 60 KiloOhm

Hence the Inductance is derived as: 160 Henry

And the ratio of reactance to resistance of this winding is derived as:
2500 Numeric

A 60 cycle condenser bank is now constructed to give an equal and opposite reactance to that of the 60 KV secondary coil. At 60 KV the reactive power in this winding is:
60 KiloVars

Thus the condenser must also develop a counteracting power,
60 KiloVars

And this results from a condenser reactance of:
60 Kilo-Ohm
The same as that in the transformer winding. Finally, this condenser bank must withstand the basic impulse level developed by the secondary winding, a maximum of
300 KiloVolts

Hence established is a series connected condenser bank, of ten 30 KV units, each with a capacity of
.4 microFarads

Or a total of .04 microFarads.

Here now in the transformer yard is our experimental network, about 50 tons in weight.

The test voltage in the experiments will be 120 volts AC, 60 cycles per second, from a lighting transformer.

The first experiment is shown in Figure (2). The 120 volts is connected to the secondary winding of the transformer. The current is the voltage divided by the reactance,
2 mA

Now in place of the transformer winding, the condenser is connected the 120 volt supply. The current is also
2 mA

The Back E.M.F. of both the coil and the condenser are equal since the reactance of the coil and condenser are equal. Here however it is equal and opposite.

The next experimental setup is shown in figure (3). Here now the condenser is connected in series with the winding of the transformer. It is found that a current of
5 Amperes

is now being delivered by the 120 volt supply. The transformer is emitting a deep, powerful, growl and the condenser bank is crackling with static sparks. The voltage on the line bushing is measured to be
300 KiloVolts.
The maximum voltage of the transformer.

HOLY TESLA MR WIZARD!! WHAT HAPPENED?!!

The electrical network utilized is shown in figure (4). It is a basic series RLC circuit;
Resistance, 24 Ohm
Inductance, 160 Henry
Capacitance, 0.04 microFarad

Shown in figure (4) is the remarkable condition that the full line voltage of 120 volts appears across the resistor, just as if the coil and condenser **DID NOT EVEN EXIST**. Also interesting is that the high voltage of the coil counteracts the high voltage of the condenser giving a net voltage of zero.

The Electromotive force developed by the coil is the current times the reactance,
5 Ampere, 60 Kilo-Ohm
300 KiloVolt

Likewise the electrostatic potential contained by the condenser is the current times the reactance,
5 Ampere, 60 Kilo-Ohm
300 KiloVolt

The real power of energy consumption is the product of the E.M.F. and current dissipated by the resistance
600 watt

The image power of energy storage is the product of the voltage developed times the current developing the voltage, E.M.F. or potential
1500 KiloVolt-Amperes

Taking the ratios gives the voltage magnification,
300 KV per 120V,
or 2500 numeric

And the power magnification,
1500 KVar per 600 Watt, or
2500 numeric.

To summarize, today in the D.W.P. transformer yard we simulated a 60 cycle Tesla Transformer in lumped parameter form. This "Tesla Coil" developed a maximum potential of 300 KiloVolts with an activity of 1500 KiloVars. Its magnification factor is 2500. This system is not able to transmit however because the sum of all the currents in this setup are equal to zero in accord with Kirchoff's Law. This is a simulation only to demonstrate the basic principles of resonance as developed by Tesla.

60 KV Transformer

(1) Experiments continue today with the 3000 KVA 60 KV generating station line transformer. No information exists on the exact distributed constants within this transformer therefore the constants will be developed by the use of effective values as externally measured.

A source of variable frequency alternating current is applied to the 2.4 KV primary winding of the line transformer. The neutral, H1, of the secondary winding is grounded. An electro-static voltmeter is connected from neutral, H1, to line, H2, of the 60 KV secondary winding. It is found that the fundamental quarter wave frequency is 716 cycles per second. This is the natural frequency of the transformer.

(2) The scalar inductance was determined by 60 cycle measurement to be 160 Henry. Since the current in the winding in resonance (self) is of a sine distribution along the winding length the effective value of inductance is two divided by Pi times the scalar inductance. Hence the effective inductance is derived:
100 Henry

(3) For a frequency of 716 cycles per second the angular frequency in radians per second is two Pi times 716 giving:
5000 radians per second

The product of the inductance and the capacitance of an oscillating circuit gives the inverse of the square of the angular frequency. By algebraic operation it is hence the capacitance in Farads is given by the inverse of the product of the inductance and the square of the angular frequency. Here derived is the effective capacitance,
500 picoFarad

And since the electro-static potential also is a sine function along coil length multiplication by Pi divided by two gives the total capacitance,
785 picoFarads

These values are for 716 cycles per second only, the Pi over two, or quarter wave resonance, of the winding.

Hereby the basic energy storage constants of the transformer secondary are established for a condition of self resonance. Now rather than a 60 cycle power transformer it is a 716 cycle resonant, or Tesla, transformer.

(4) In this self resonant mode this transformer not only has a frequency in radians per second, but also has a wavelength in radians per centimeter. At 60 cycles the winding is space scalar, that is, the current is the same in each and every element of length along the winding conductor. At 716 cycles the current not only varies along the length in intensity, but also varies in phase. In terms of effective values the current at the neutral, H1, is not equal to, or in phase with, the current at the line, H2. Also at quarter wave the current is zero at the line terminal since this terminal is not connected but left free. The circuital laws of Kirchoff no longer apply and the currents no longer

sum to zero. Hereby a mono-polar current appears to ground at the neutral, H1, of the secondary winding.

(5) In order to analyse this transformer winding as a transmission network two factors must be known:

I) The propagation constant as derived from the product of the effective inductance and the effective capacitance,

II) The characteristic impedance as derived from the ratio of the effective inductance and the effective capacitance.

The propagation constant is defined by the frequency, or per second. The characteristic impedance is derived from the square root of the ratio of the effective capacitance. While the frequency is invariant if the Miller, or Steinmetz methods of determining the effective values, the impedance is not and will differ between methods of deriving effective values. For simplicity the Steinmetz method is used here. Taking the effective inductance as,
100 Henry

And the effective capacitance as,
500 picoFarad

Gives the characteristic impedance as,
450 Kilo-Ohm

This can be called the natural impedance of the secondary winding at its natural frequency of 716 cycles per second.

These are the fundamental externally established constants for the 60 KV secondary winding.

(6) Hereby the input vs output transformation of this secondary winding can be determined. The winding can now be considered a "Black Box" two terminal reactance arm, this akin to the Guillemen line shown previously. In this network of coiled windings the output potential is the input current multiplied by the natural impedance. Hence for a current applied to neutral (H1) terminal, one ampere multiplying this by 450 Kilo-Ohms gives a potential at line terminal (H2) as
450 KiloVolts

This causing the bushing spark gap to flash over. Since the B.I.L. of this transformer is 300 KV then this potential divided by the natural impedance derives the maximum permissible neutral current as,
.667 Ampere

At a frequency of 716 cycles per second. In this manner, when excited through the neutral to develop a high potential at the line, the 60 KV secondary winding is operating as an extra coil. The primary has no function in operation and therefore this is no longer a resonant transformer.

Thus this 60 KV transformer can serve two distinct functions:

I) A resonant transformer with a low voltage primary and a high voltage resonant secondary,

II) an extra coil as a single resonant high voltage winding series fed through its neutral.

60 KV Transformer, Theory:

(1) In the previous experiments two distinct forms of resonance have been demonstrated.

I) Lumped parameter resonance, circuital

II) Distributed parameter resonance, wavelength

In condition one the dielectric energy storage coefficient, capacitance, is external to the winding structure. The current IN at H1 is the current OUT at H2. There is no difference in magnitude, nor any displacement in time between the currents at H1 and those at H2, the same current.

In condition two the dielectric energy storage is within the winding structure and that in the space between the winding and the core and tank. This can no longer be expressed as a capacitance in the normal sense of the word. Dielectric energy storage is now a complex quantity in the dimension of space. For the most part is is inscrutable and all that can be measured outside of the tank is the effective capacitance at a given operating frequency. A graphic illustration is given by Tesla in his "True Wireless" extract. The effective capacitance of a coiled winding is the square root of the ratio of the capacitance, C, from winding to core and tank, and the elastance, K (in per Farad), existing within the interturn counterspace. Hence, Farad per, per Farad, the square root of which gives the effective capacity. In static or D.C. operation the energy storage coefficient, K, vanishes, leaving only the self capacitance, C. This measure as the static capacitance of the transformer winding. Hence the effective capacitance is a function fo the time rate of energy exchange. It is important to recognize here that a Pure Dilectric Wave exists. The space distribution of dielectric induction is given by the propagation constant. This constant is a Time Scalar, that is, the formation of this dielectric distribution is instantaneous from end to end on the coiled winding. No magnetic induction exists here.

(2) The lumped parameter condition lends itself to circuital representation. Series coefficients are

given as inductance, L, and elastance, K, Henry and per Farad. Shunt coefficients are given as Enductance, M, and Capacitance, C, per Henry and Farad.

The components that comprise the circuit are lumped, or Space Scalar. The shape, size, geometry, and etc. play no definite role in the energy storage coefficients. In the magnetic "components" the dielectric field is forced out of existence, and likewise in the dielectric "components" the magnetic field is forced out of existence. The magnetic wants an expansive space, the dielectric wants a contractive space. See "Disruptive Discharges" in my Four Quadrant writing. Review This.

(3) The distributed parameter condition CANNOT be given as a circuital representation. Inductance and Capacitance lose their common meaning and can only be expressed as effective values, such as derived from space integrals. The magnetic and dielectric energy storagecoefficients now exist in a different set of dimensions, as space derivatives of the energy storage coefficients. Dimensionally it is;

Magnetic
I) Distributed Inductance: Henry per centimeter
II) Distributed Enductance: per Henry-centimeter

and Dielectric
III) Distributed capacitance: Farad per centimeter
IV) Distributed Elastance: per Farad-centimeter

The designations, C, K, L, M, are to be taken on this per centimeter basis when expressing energy storage in distributed form.

It is of interest to note here that, L, and, C, now are dimensionally equivalent to the magnetic permeability, and the dielectric permittivity,

Mu, or Henry per centimeter
Epsilon, or Farad per centimeter

Hence these coefficients, L, and, C, are akin to the one over C square relation of electro-magnetic wave propagation. Conversely M, and, K, are of a unique dimensional constitution and K, is more akin to a sound wave condition. The product of, M, and K, do not yield an electro-magnetic condition, there is no per velocity square as given by the product of, L, and, C. The dimensional relation of, M, and, K, yield a magneto-dielectric condition as a per counter-velocity square. Hence if velocity is given as

C, in miles per hour

It is that counter-velocity is given as

u, in per mile per hour.

These propagations exist at right angles to each other on the coiled winding in a Four "dimensional" space as the physic would like to say. This complex configuration defies any existing analysis.

(3) Here in the winding with distributed constants exists a transmission line condition, propagation is involved from one end of the winding, H1, to the other end of the winding, H2.

It is however, that this propagation not only exists in space, such as a two wire phone line, but now also exists in counter-space. The dimensional relation of velocity no longer has meaning in defining this propagation. These considerations are the primary stumbling blocks to resonant transformer calculations. The physicist declares the situation as "incapable of being treated by mathematics" and thus declares it impossible to exist. Then comes ridicule, and finally totalitarian suppresion, AKA Al-Gorda.

4) Now it is left to the experimenter. Tesla knew very little of what has just been given here on the resonance of windings. He had one foot in lumped constants, and the other foot in distributed constants, and no measuring instruments that are taken for granted today. It can be plainly seen that here is a transmission line problem, just taken to the next level. Basic two wire line theory is almost beyond human conception as plainly given by Heaviside, Steinmetz, and Guillemen, in thousands of pages. Now it goes octaves deeper.

60 KV Transformer, Final

(1) Given in the previous transmissions is that there exists three distinct modes in which this transformer can operate.

I) As a power transformer for machine frequencies. The inductance is space scalar and the dielectric energy content is negligible.

II) As a resonant transformer for VLF frequencies. The inductance is a sine function of space and a considerable quantity of dielectric energy content exists, equal to the magnetic energy content. The capacitance is now a cosine function of distance. This resonant energy exchange is powered by a loose coupled source of Alternating Current through the primary winding.

III) As an extra coil for VLF frequencies. Again equal energies in a resonant exchange but now series fed through the neutral to earth connection. The primary coil now is inactive in this operation.

2) Some further experiments are in order here.

The DC, or static, resistance of the 60 KV secondary winding is measured to be:
24 Ohm

Handy is a car battery:
12 Volt

Now connecting the line, H2, terminal to its line vacuum breaker, Figure 1, and connecting the line side of the breaker to the positive terminal of the car battery, a basic current loop is formed.

The negative terminal of the car battery is connected to an ammeter and then to the transformer neutral. The neutral, H1, is grounded to station ground.

3) The vacuum breaker is closed completing the current loop, this loop a basic, L,R, circuit of 24 Ohm and 160 Henry. Upon closure a stopwatch counts time from the instant of this closure, T, equals zero. Observing the ammeter it is seen to rise very slowly. At the point when the ammeter reads
316 milliAmpere

The stopwatch is checked. The span of time to reach 63.2 percent of the maximum value is called the magnetic time constant, u. The stopwatch reads
6.7 seconds

The ammeter continues to climb, in ever smaller increments closer and closer to 500 milliAmp. It is noticed it takes over 33 seconds for the inductance to reach full charge. See figure 63.

At full charge the winding current is one half Ampere. The static winding inductance is 160 Henry. Hence the magnetic energy storage is derived as
20 Watt-second

4) Now the vacuum breaker is tripped, this instantaneously breaking the loop. A streamer several feet long erupts from the line, H2, bushing insto space. Since no escape of energy exists the magnetic energy is abruptly converted into dielectric energy at a fundamental frequency and its odd order harmonics. This was given as
716 cycles per second

The effective values of inductance and capacitance were determined to be 100 Henry
and
500 picoFarad

By the law of conservation of energy the magnetic energy equals the dielectric energy. By algebraic operation the ratio of EMF to current is the square root of the ratio of 100 Henry and

500 picoFarad,
450 Kilo_ohm

And thus from a 12 Volt car battery the EMF developed at the line terminal, H2, is derived as
225 KiloVolts peak

This assuming a sinusoidal waveform. Here the harmonics were burned off in the streamer issuing from H2.

(5) The increase in frequency from 60 cycle to 716 cycle gives an increase of the effective resistance to 72 Ohm, at 716 cycles per second. The effective inductance is 100 Henry. The reactance of this inductance at the oscillating frequency, Omega,
4500 radians per second

is derived to be Omega L or
450 Kilo-Ohm

And the time constant of the 716 cycle oscillation is derived from the effective inductance in proportion to the effective resistance, L, over, R. It is however that the oscillatory energy is magnetic only half the time, the other half is dielectric. Hence the time constant is given as one half the ration of inductance to resistance, one half of
1.39

Gives the oscillatory time constant as,
.7 seconds

At this time the magnitude of the oscillation has diminished to one over Epsilon, or
36.8 percent

The oscillation becomes inaudible in about five times this, or,
3.5 seconds

See figure 60.

(6) The magnification factor of this oscillating winding is determined by the ratio of the effective winding reactance to the effective winding resistance,
450 Kilo-Ohm
to
72 Ohm
Giving
6250 numeric

The initial, or peak, current is one half an ampere this the effective value, or per square root of two, is given,
356 milliAmpere RMS

The initial, or peak, EMF is given as 225 Kilo-Volt, hence the effective value is,
159 Kilo-Volt, RMS

The product of these values gives the total oscillatory activity in the transformer winding,
56.6 Kilo-Volt-Ampere

(7) The losses in the windings are given by the square of the effective current times the effective resistance, I squared R, or the Back EMF developed by the losses is the current times the resistance, I, times, R, or

25.6 Volt

Here from are derived the basic transformation parameters in the operation of the 60 KV secondary winding as a resonant extra coil, this for an output potential of 160 KV at 716 cycles per second.

Input (H1) Power Requirement
9.1 Watt

Input Impedance, E, over, I, or,
72 Ohm

This a resistive load as seen by the source of alternating electric energy. Hence, a 10 watt audio amplifier, on the 50 Ohm output tap, will give rise to a resonant oscillation, building up over a time span of 3.5 seconds, this with an activity of 56.6 KiloVars and an electrostatic potential of 160 KiloVolts. Here established is the concept, -- "Magnification Transformer"

Crysta Radio Magic

Well it's not magic(sorry 4 the deception) but it is a radio, my first. It works and I can hear the one station I was hoping for; 1620kHz, 10,000 watts, 6 miles away.

I started this because of
Quote:

> Originally Posted by **T-rex**
> *Here is how the contest works. We learn how to make a "Crystal Set", just as everybody should. It is a "Rite of Passage". A crystal set is an A.M. radio that uses no battery, the magnification factor of its tank circuit powers the radio. Hence it can be seen that the A.M. broadcast station's transmitted energy is powering the crystal set, JUST AS TESLA ENVISIONED. Wow Mr. Wizard that is fantastic. Let's start today.*
> *Break more to follow*

Problem: It was easy, very easy. No matter what I do I can hear this station. I was expecting to have to "tune in" this station. So instead I minimized the components. An inductor(300uH, 60 turns, 20gauge), 1N34 germanium diode, crystal ear bud, and antenna(just about everything works(10 feet of 20 gauge, my body, cookie sheet, and even a beer can)) Some work better than others.
No capacitor??? Holding the coil is the best capacitor I found.
No ground. If I connect it to ground I either get a 60Hz hum when I use a water pipe or lower volume if I stick 2 feet of 6 gauge in the ground. I guess that means I need a better ground. Off to home depot for 10' water pipes.

Two questions for the group: (the goal is to maximize the reception of 1620kHz with only a crystal ear piece)

-There are a number of online calculators that allow you to calculate capatance for a given inductance or inductance for a given capatance, both for a given frequency? What "ratio" works best? (is it better to have more capatance or more inductance).

-Ground-What is good enough? Does it keep getting better as your ground system grows and gets deeper. Is it better to go deeper or wider(radial star like Dollard describes) I have lots of clay around here and I am going to try to water drill with the copper pipe as it goes down. How much better would 20' be over 10'?

Ok more than 2 questions but I'm learning.

Hi Jake,

Your biggest "problem" (may sound strange) is your closeness to the 10kW AM station... I mean the station makes too much field strength this is why almost anything behaves like an antenna, touching the coil makes big changes, etc.

First I would suggest using a coupling coil of 10-15 turns, placed to the bottom of your big air core coil, this coupling coil upper wire end would be connected to a 1 or 2m long wire (this latter serves as an antenna) and the lower end would go to Earth. Do not connect the big coil lower end to the coupling coil's earth point, ok?
Then you should find the capacitor needed for resonating your big coil to be a parallel LC circuit at 1620kHz. If you have now 300uH, then you would need 32.2pF to tune it to 1620kHz, the best would be to use a 40pF or 60pF trimmer capacitor. See link later for online LC calculator.

Then see this schematic here and I suggest making another 20-22 turn coil (not critical) onto your big air core coil, also to its bottom part, maybe over to the coupling coil mentioned above, this newer coil would serve as the L4 coil does in this schematic:
http://hibp.ecse.rpi.edu/~john/hi_power_xtal_set.gif
and you would need the diodes D1, D2, C3 and C4 of course, your crystal earpiece would connect to points A and B directly. (Do not connect this second coil to the earth point either.)

See this link where the schematics is referred to, it may be useful reading for you: High-Power Crystal Radio

I think your water tap earth is good enough but connect it ONLY to the antenna coupling coil I mentioned making first above, then you should not have 60Hz hum.

Another possibility is to use an AM ferrite antenna, like seen here:
Scotts Electronics Ferrite Loopstick Antenna Coil Crystal Radio Coils AM Coils but if you google you can find elsewhere too. Of course you do not have to make any antenna coupling coil for it, the Litze wire coil on the rod completes the antenna and if you choose the 680uh Litz wire coil with a tap at 470uh about 20 turns from end, then this 20 turn can serve as L4 for the diodes (you can separate the two wires which led out as a twisted wire to make the tap). This 680uH ferrite antenna needs 14pF capacitor across it.
I used this online calculator:
LC Resonance Calculator
(Notice the L value needs to be entered in nH, not in uH and f is in MHz.)

Normally it is better here to use higher L and lower C values but because of you want to receive a station at the very edge of the AM band the usual coils used for AM reception seems too high in value this is why so small pF value the tuning capacitor has (14pF or 32pF). You may wish to remove say 10-15 turns from your 60 turn air core coil to reduce its inductance and then increase the tuning cap higher or when using ferrite antenna the coil on the rod can be slided a bit off towards and / or beyond the rod's edge. The small cap values needed for 1620kHz resonance with such 300-680uH coils explain why you found good reception when you were holding the coil: your hand and body capacitance, your close presence to the coil supplied the 32pF tuning...

Hope this helps,

Gyula

Extra thanks

That is exactly the kind of advice I was looking for. I appreciate it very much. I suffered information overload when I tried searching for the "ideal" capatance/inductance ratio. There are just so many ways to do it there does not seem to be an ideal way.

Im off to snip, tap, wind, and take off some turns.

Thanks,

Whats the ground for?

I mean: I know what the ground is for but if you can receive a radio signal fine without a ground connection what additional benefit would you get if you attache to a good ground??

IF you can receive a station fine without ground connection, then I do not think you need ground for THAT station. I think it all depends on the sufficient field strength for a radio station at a particular location, a good ground can contribute to a much better reception (in a given receiving

antenna case) when you wish to listen to a distant station which does not have a strong field 'presence' at your location.
What additional benefit? In your 6 miles away station case probably nothing (I have never had such chance lol), though you could probably use an even shorter piece of wire when you have a good ground. Remember the station transmitter antenna for the AM bands usually works against a big ground system and an isolated metal tower of a given vertical length is the radiator. So in a distant station case you can benefit from grounding because radiated station energy is taken also from the ground, not only from the 'air'.

A Tesla receiver won't work without the ground because it's designed to receive the underground signal. Herein lies the fallacy of so-called "wireless energy transmission"

next generation crystal radio

So once I felt confortable with a typical crystal radio and could tune most of the stations on the high end of the AM band. I started to put together a Tesla Resonant Transformer. This is part of the crystal initative on the Dollard Thread.

Below are the results of three generations of coil formers. The former you see is stout and will allow you to pull the wire tight while winding. I am still missing the primary, topload, capacitors. BUT

It blows my crystal radio with tuning capacitor away. Attached are some pics. The DSO pic is my night time reception it came down from 1.3v earlier this afternoon with +4v peaks. This got me excited for a while but then I realized that my scope maxes out at 1MHz. Your looking at 1.62MHz rectified
audio. 100us/div and 50mv/div, the yellow line is 500mv.

Do these numbers mean anything or is working out of the range of my scope produce garbage numbrs???

And finally I was able to dimly light an LED in line with the germanium diode.

Any one know how to hook up a joule theif without loading down the circuit??

It looks like there is enought there to run one but doing it without loading down the circuit is eluding me.

the primary coil is key to the ground receptive part of the set. the primary and secondary resonate and based on the capacitance and geometry the radiation resistance will be eliminated in the extra coil giving rise to FTL reception. On my set the primary is not large enough as I based it purely on surface area however after reading the reports of others and noting their relations and the effects between my set, I tentatively state that the surface area of winding capacitance is what needs to me matched, not the bulk surface area. I'm working on the equations to see what this turns up. I'm also looking at the skin effect and mass as well, no point in leaving any stone unturned.

Nice build btw, looks good. the extra coils is such a PITA to wind too. I wouldn't worry about 'skip' distance from being too close to the transmitter in fact I'd say that's a prime example of ground current reception, proof that this works.

I personally have the set built but have not gotten the results I want, however it's not been without results as it as given me answers to questions on capacitance by noting the differences in my results to others. however lets say we have one build that is catalog'd and every parameter of the physical construction known. from that it can be altered and the changes noted and then using that it can direct the mathematics to derive the needed equations to refine and move forward.*
>
> *right now the one thing I've seen is the surface area and capacitance equations, capacitance is frustrating itself as it's always an assumed infinite plane yet we know it's not. high frequency skin effect and resistance of the mass of the 'director' and the geometry all play a role, as seen it gets very complex. I've spent a couple hundred hrs already on just calculations and have now just started to notice a few things I'd like to explore, with some more research into hyperbolic trig I may have some equations that can be tested in the field. I'll share this freely with anyone willing to test on their crystal sets. ultimately I'd like to see if we can all build matching sets and see if we can network them together as Tesla intended.*

I am thinking the same thing. Matching sets would get noticed. Im thinking somewhere in the 2-3MHz range. That would make everything smaller and the brass shim stock would fit the bill. You could put that together for under 50 bucks. But we'd have to find a transmitter for the testing.

but before we get too far ahead of ourselves. We need to light an indicator bulb.

As far as my build. I am still looking for a long enough flat piece of copper.. I sent out a few emails looking for overruns, but the standard size seems to be 100" and I need 118". I found a thin walled copper tube at the scrap yard and bought enough.. Ive been contemplating slicing it open and flattening it out.

and now back to what I think was your point. The math needed to go along with the cyrstal initative. I want it. Been doing lots of thinking.

Lets start simple.. and I am really look forward to hearing from all those interested..

How do you calculate the C and K of a TRT secondary?
How do you calculate the L and M of a TRT secondary?
i.e. 20 turns(T), wire diameter(d) in mm, turn gap(g) in mm,

Can we even use the standard inductance and capacitance equations or are they contaminated?
bring on the versors

Ill post my answer tomorrow? after I watch the SFTS videos If i can think of one.

Here is where hyperbolic algebra come in, Alexander Macfarlane has some very good books on hyperbolic and elliptical algebra. useful eq. for adapting to the coils can be found in Kennelys work as he does utilize Steinmetz and Heaviside's operators making it easier to cross reference his work.

the complex quantities notes of Steinmetz are also very helpful in explaining the j operator and power of the square root of -1.

Thats where I am having trouble. I need to study.

So if all the adapting and math is down would it be able to calculate "values" for C,K,L,M and thier ratios at any point during the cycle of a TRT??? <---Please answer pretty please.. any one. What are the roadblocks?

That would help enormously in tuning the setup. It's almost impossible to tune three coils with 4 parameters that are changing without having either a solid math foundation or a natural ability to feel what you are doing. I'm working with the former at the moment. I'm not thinking about numbers; just C,K,M,L and what they are doing at every spot in the setup at every point in the cycle and and how I can add, reduce, and change their "rate".

Am I talking jibberish? or just a few months behind.
currently rewatching video 3 of the SFTS.

Also regarding the surface area aspect... Don't give up on mass just yet. Tesla's use of the word "stout" appears in lots of primaries.

My primary was calculated to 3m by 8.4cm by 0.1mm for a grand total of 26.4 cm^3.. Does that sound stout to you?

parametric changes are nearly impossible to calculate as they would occur on the fly and you'd need to run a simulator to get close. there is no program in existence that can do that for these parameters. you can get a rough layout that would need 'tuning' with the math and knowledge available at the moment.

Hyperbolic geometry is closer to nature, the cantenary slope is a prime example. a rope hung between two points exhibits this form. what also needs to be added into the equation is counter-space, due to the time invariant 'dimension' of the dielectric.

I'm still researching every day, it's an undeveloped field. the majority of mathematics of manifolds and abstract algebra all conform to relativity, that makes it that much harder to develop a working set of equations as one needs to filter out the conforming terms and relations. it's mighty pervasive, one of the reasons why the bulk of reference material is pre-1927.

around the turn of the century there was a divide on quaternions as well, Alexander Macfarlane also postulated with hyperbolic quaternions and that can be seen in his lectures on the mathematics of space.

so an abstract non relativistic conforming algebraic hyperbolic counter-space geometry needs to be developed it would seem. a simple thing really

I don't abide by the reductionist view of quantum physics or a static state. we exist in a dynamic interconnected manifold, one change effects all. any equations that try to handle this will have a type of 'Heisenberg' uncertainty to use it loosely, it's ever changing and a static 'snapshot' will not explain the dynamic relations. personally I think true advancement will occur when apparatus become 'living' not sentient but more organic. loose terms there, but think of a plant vs a solar panel, the solar panel is rigidly fixed in it's parameters where the plant can adapt and change as needed constantly.

I've diverged enough there. To make any real gains a framework needs to be developed to model the manifold of the dielectric and then develop the basics of each phenomen, i.e. the e,E,I,i k K,c etc...

Does anyone have tips for soldering 14ga solid to 1/2" copper pipe?

Do you wrap the wire around the pipe and solder all the way around or just solder ~1/2" however???

Still trying to calculate MKLC. Watching SFTS videos again this time taking notes.

@ mad

What do you mean by manifold?

Hi Jake,

To solder together thick pieces of solder , an ordinary soldering iron just does not provide enough heat as the heat gets dissipated into the thicker material too easily.
Use a propane torch -like what plumbers use to solder copper pipe fittings.
Also , make sure that the copper pipe is lightly sanded at the area you want to soldered -to get rid of the oxidization---or use that flux paste plumbers use to help clean off the oxidization while it's being soldered . Good luck--[I] hope this helps.

I this typical RF

On a TRT secondary and extra coil:

{extra coil}------{secondary}-----Ground

If I tap between the extra coil and secondary run a germanium diode, my body, and LED in series to ground I can dimly light the led.

{top of secondary}--{+germanium diode-}---{right hand}---{body}----{left hand}---{+LED-}----Ground

The LED will show light and its getting brighter the more I learn.

Is this a normal RF???

I can see 2.2v avg across the LED when I leave my body out of the circuit. 2.6max and 2.5pp. These are all estimated because the values fluctuate with the broadcast signal. They stabalize a bit when I put a 330pF cap across the LED.
Also adding capacitance to the lead that goes from secondary to diode in the form of me touching the insulated lead has a large effect. I was able to recreate this effect using a the piece of aluminium(i.e. the ground terminals of a dule gang air variable cap). Using the variable cap the way it should be used did not work. Made things completely stop working and the voltage dissapear. I found this on accident.

So is this something you would see on a typical crystal radio?
Is it RF or somethine else?

Not unless the antenna was near a strong RF source. Do you have any radio or TV transmit towers near you? If you watch MrFlathunter (Seth) videos you will see he is able to light things with his passive resonator but only if near the transmitting exciter.

I have a 10kw AM station about 6 miles away. I looked up mrflathunter and found two more that show similar results of dimly lighting LEDs with nothing but a coil and diode. Do you have any advice on how to run a joule theif off these? I listed the voltages I can measure above.

Solder wire to standoff. Attach standoff to pipe with screw.

I have posted a number of low power Joule thief circuits. This may be a good choice ... no toroid Joule thief 3 - YouTube

Rectify radio output with diode and capacitor. Run Joule thief from capacitor. You will need at least 0.5 to 0.7 volts to run Joule thief. You do not need 10,000 uF capacitor, use what ever you have. Reduce resistor value to make LED brighter.

Same circuit with toroid >> 2 uA Joule thief - YouTube

Wish I had seen that before I untwisted 500 feet of 20 gauge bell wire. That would have been fun to try with 500'.

Thanks,

I said this in the other thread, make a ful wave bridge out of your germ diodes and use filter caps. I would be shocked if you couls pull in any amount of power like that because of the low current density. The whole idea of pulling "significant" power off of these radio stations seems absurd to me.

It will give you filtered dc, then you can do with it what you want.

you know thinking about it you may not be able to do a fw bridge, maybe only 1/2 wave, I forget the ckt config.

The whole idea of pulling "significant" power off of these radio stations seems absurd to me.*

That's what I'm trying to figure out.

File:Replica-of-first-transistor.jpg - Wikipedia, the free encyclopedia

I like this picture. It says alot about what we can do once we learn how.

I've learned alot about working with radio frequency just tuning the basic crystal radio.

So far my TRT is a Just a large crystal radio with two coils. But it will light an LED continuously all day when the station is @ 10kW. It's dim but it's on. Not blinking(filter cap), one germanium diode and led across the secondary.

It may all be just standard RF reception. I don't know yet. I didn't think that would be possible. But it's not tuned yet. Unless I got it right the first rime.

The full wave should help as long as the extra voltage drop does not cause problems.

Thanks,

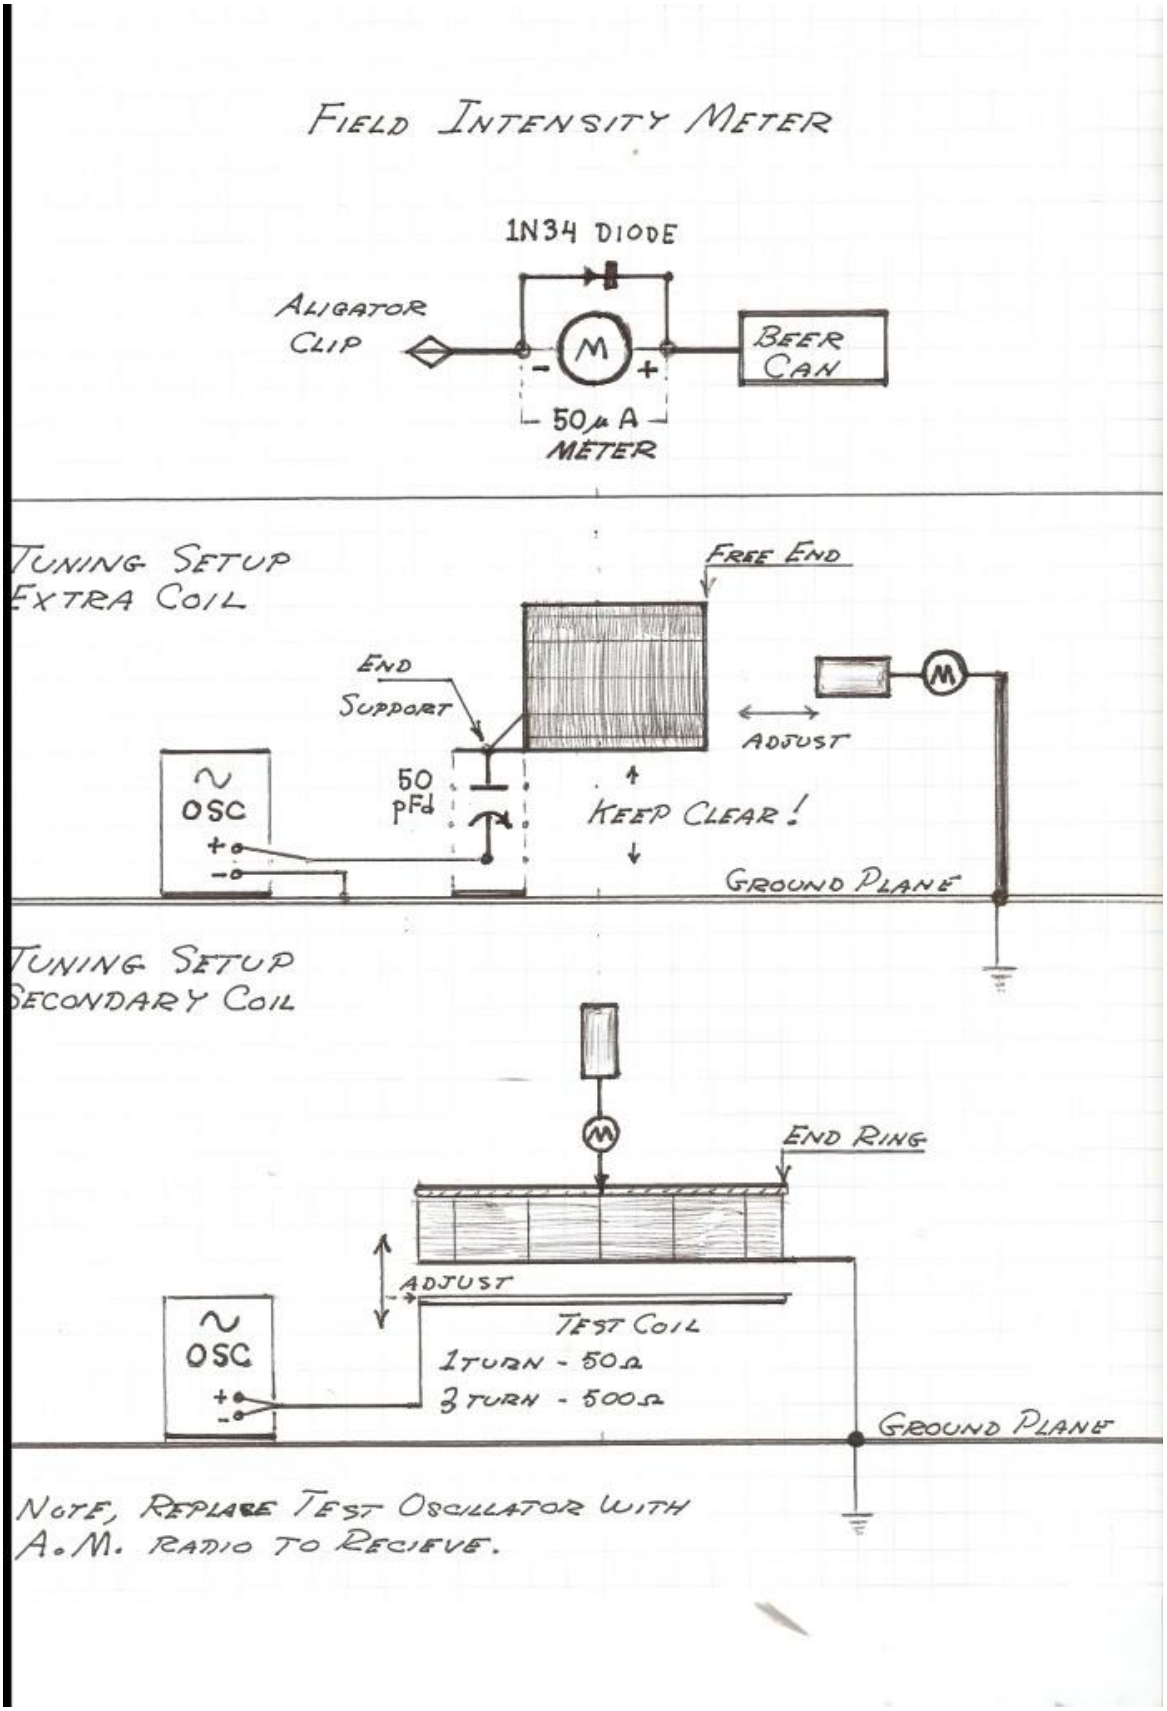
Why?

As the distance between the primary and secondary is increased the resonant frequency of the coil increases ~5-10kHz per inch and the amperage measured between the can and the top of the secondary also goes up.

Any ideas?

I'm playing with the secondary and primary like in



FIELD INTENSITY METER
1N34 DIODE
ALIGATOR CLIP
M
-
+
BEER CAN
50µA METER
TUNING SETUP EXTRA COIL
FREE END
END SUPPORT
M
ADJUST
50 pFd
OSC
+
-
KEEP CLEAR!
GROUND PLANE
TUNING SETUP SECONDARY COIL
M
END RING
ADJUST
OSC
+
-
TEST COIL
1 TURN - 50Ω
3 TURN - 500Ω
GROUND PLANE
NOTE, REPLACE TEST OSCILLATOR WITH A.M. RADIO TO RECIEVE.

I did not post this in the Dollard thread because I am missing the split ring on top. I am also using more of a current indicator with an adjustable range for readings so there are no actual values I cam use.

Currently the best frequency is 2300kHz. But this will change (+) 500kHz) depending on the coil

Getting Better

I'm getting lonely. Is anyone else getting ANY results out of the crystal radio initiative setup?

Nice drawings.

When the two coils are close they "load" each other. This increases inductance of each coil, decreases Q of resonators, and provides more energy transfer between coils. In crystal radios increasing coupling between coils will provide more energy transfer but also decrease resonator Q. Usually minimum coupling is best since this produces highest resonator Q. If both coils are resonant at the same frequency then the Q of one coil will increase the effective Q of the other coil. This is how coupled resonator filters work. But the resonant frequency will change as the coils are brought closer together so they must be re-tuned after they are moved closer together.

I suggest you try coupling two parallel resonant circuits and tune to same frequency. This should give improved reception. Best if you can tune to frequency of near by radio station.

Or just make one parallel resonant circuit with large coil and weakly couple to it with a single loop or a small capacitor.

I would think your power detector would work better if the diode was in series with the amp meter. The circuit you have would work with a volt meter.

Please keep posting your results. I hope you will be able to light an LED from the RF signal.

Jake,

Eric said that it is not easy to get three coils to resonate together. It took him about a year at Landers to properly tune his receiver. As xee2 was saying, your magnification factor (Q) will be much higher if you can get the coils into a symbiotic resonance. This heightened magnification factor is apparently what allowed Eric to light the light bulb.

He also said that if you are having trouble getting these coils to resonate then don't use the extra coil and it would still work. However, I don't know if this will light a light bulb without the heightened magnification factor. This might just be for a telluric receiver.

Have you tried using an aerial (dipole) and the TMT style antenna at the same time for a comparison on an oscilloscope? This is what Eric is talking about in order to see the difference in phase angle of the two signals to see that the telluric transmission is propagated faster than the above ground transmission. This would be the evidence of a faster than light propagation.

The credit for the drawings goes to Eric Dollard. Those are his pictures from the Dollard thread.

And the LED is lit. I am able to take the large 20 turn coil and attach it to either my fireplace or stove vent hood or large metal object(i.e. antenna) and light an LED to a decent glow. It is not full brightness but it was constant and even my wife freaked out a little when I said there was no battery. The other end of the coil has a Dr Pep can.

My first attemts to get a joule thief to brighten up the light were a failure but I will revisit the JT idea a little later as attaching the coil to an antenna now allowes me to light the LED to a level that does not require the JT.

Without attaching to an antenna I can only sometimes get a very faint glow.

ALSO this coil is not resonant at 1620kHz. This is the station that is supplying the power. It is 10kw more than 5 miles away. And at night it goes down to 1kw. Even at night I can see very very faint blips of the LED.

The coil attached to the fireplace surround and DP can is resonant at ~2200kHz depending on where and how I excite it. I KNOW that LED will go balistic if I can get it tuned to 1620. Using a function generator at 1620 will not light the led. Turning it to 2200 will light the LED beyond a glow and one might say bright enough.

PROBLEM!! - Tuning for brightness does not seem to like external capacitors and REALLY does not like alligator clip leads. To get it to where it is now required respacing the turns of the coil and tapping the coil in the right spot. but even that does not let it drop down to 1620

Eventually when I figure out how to tune the coil without needing capacitors I will move on to the extra coil. Using the extra coil now will either help or hinder depending on what I have going on. So I took it off and will revist it when I get the secondary(large 20 turn coil) to 1620.

I saw this post after I posted my last post.

It is quite a troubleshooting mission to tune three coils. I am having extream difficulty tuning one and I don't even know if I am doing that right. but I think I am getting a feel for it. Its hard to tell how much of the tuning should be done with distributed elements alone. As I noted in my last post adding a capacitor no matter how tiny seems to reduce performance. Putting my hand ~1" from the soda can peaks performance. Touching the can kills it.

I have assembled all that is necessary for version 2. It will be the same dimensions as the first unless I can figure out how to lower the resonant frequency about 400kHz. Instead of using 14ga I will be using 2.21mm OD x 0.91mm ID copper tubing. This will more than double the active copper compared to what I have now. I don't know how important that is but it feels right. The primary will have slightly more and can be narrowed down to match. Same for the copper plate primary cap. Now thats a lot of copper. Trust me I have been buying it by the pound at the scrap yard as it comes in.

I do not have a scope capable of the comparison. But I am sure if I can light a 100w light bulb my wife will let me buy one.

Thanks for the input.

Use a metal plate connected to earth/bottom of the secondary with adjustable distance from the can, and position it for peak performance. It won't like a variable cap very much across the secondary (unless maybe it actually goes down to zero pF), the type with rotating plates. I think vacuum variable caps might be usable here but they are expensive, so a metal plate near the can should do the trick. You can also lower the frequency by using a bigger can/pieces of metal. I think it's the surface area that applies in this case. Try connecting progressively larger pieces of metal and see what happens.

Also the bulb that Eric has recommended since is 28v 1.12 watt. I think that will be quite a task. The most I've seen on the scope with my flat spiral coil is 210mV so there's no possibility of lighting the bulb with that. I expect I need much better grounding which will be done at some point, but there's no way of adjusting the windings either so that's about the most I'll be able to do with that coil for the moment. [edit] Although I'm not entirely sure if it will even be possible with a flat spiral at all

I assume that you are using the resonance detection method that Eric had me post recently?

As far dropping the resonant frequency of your coil, Eric had nothing to go off of except his memory for developing those formulas for design parameters. This is all in the experimental stage of getting these formulas correct. It is possible that you need to readjust the constants given by Eric by setting the coil dimensions equal to the measured resonance/constant relations and solve for a new constant. Then you could more precisely target the desired frequency in your next build. That is what I would do anyway if I were trying to adjust the frequency.

Are you trying to parallel a cap with the secondary? I think it needs to resonate at the desired frequency without a cap.

Also, are you finding that there are two resonant frequencies for the secondary that exist in a pi/2 proportionate relation?

It is hard to catch every detail that Eric throws me when I speak to him, but I am almost certain that there needs to be an extra coil in order to get the magnification factor to skyrocket which will in turn light the light bulb. I don't think I've seen an extra coil on your setup, or have I?

Yes there is another point at ~7200kHz. It's small by comparison to the other.

I was using the method you posted for the secondary to the best of my knoledge. But that's not much. Here is what I did:

For the test coil I used a pretty stout flat copper strip. I could only get it around two times. Placing the function generator across 1 turn of the test coil I set it to work. (always wanted to say that) I was not sure what the 50ohms was for but I figured it was accounted for by the 50 in the function generator.

Come to think of it I was not grounded. Or not grounded well. I will try again tomorrow outside where I have a semi decent ground. Am I correct about the 50ohms? Does the size of wire on the test coil matter?

And yes I have/had an extra coil. I took it off and things started to get better. That's when I realized something was wrong. Then you posted the tuning diagrams and I left it off. But the wire loosened up and now it has shorts all over the place. I'm using uninsulated wire for everything. I think I will move to insulated on my next extra coil.

That is not the frequency that I'm looking for. See if your meter shows *any* response around 1400 KHz or 3455 KHz.

I could be wrong but I think that there is not supposed to be a resistor in the excitation loop since there is no symbolic representation of one in the drawing. My interpretation of it is that if you have a function generator with an impedance of 50 ohm then you would use a 1 turn loop with no resistor and for 500 ohm impedance a 3 turn loop with no resistor. This is because you are interested in delivering the magnetizing force to the loop rather than trying to get a maximum power transfer between the oscillator and the excitation loop (where the majority of power would be delivered to the resistance). Try it with and without the resistor just to see if there is a difference.

Also, nobody will light a lightbulb without a GOOD ground. When I was quizzing Eric about how good a 'good ground' might be he said that the ground is a horrible conductor of electricity and that what you are really doing is creating a capacitive coupling to the Earth with the wires so make sure you have PLENTY of wires laying down against or buried in the Earth.

To lower frequency just increase inductance (increase number of turns keeping everything else the same).

Suggestion: make coil with a lot of extra turns and then cut off turns until the frequency is where you want it.

Awesome

@ Web000x:
Good Grounding is on the horizon. What do you think of Eric's recommendation of the 80 ground radials? Is this needed in addition to the 16 ground rods or can this be used in place of the 16 rods. It would be easier to lay out compared to the rods. but the center rod will be 10-20' deep in good soil.

@ xee2:
I wish it was that easy. Problem is the coil I am using now was calculated to have a specific diameter, hight and length. I can't change one without screwing up the others.

BUT I have a slightly smaller diameter cardboard tube. I think it would be a good idea to build a setup based on you way of thinking then I could compare the two. Smaller diameter will allow more turns greater induction for same length of wire.
Can't wait to get out of work.

It sounds like he is saying that the 16 ground rods should be used if you are in a place that stays relatively moist. If the ground is dry sand or rock, you need to use the 80 ground rods of 14 gauge wire. I don't see why you could not use the 80 rod configuration in normal soil. (But I am also not Eric. I'll ask when he calls me next)

Be careful about using solid tubing to wrap coils. The dielectric constant needs to be a minimum. Anything above relative dielectric constant = 1 will retard the wave. This is why Eric builds all of his transformers with wooden dowels, to expose the wires to the dielectric constant of air.

What is it?

So now I can light the LED to a continious glow at night when the statio is at 1000w. The larger primary made that happen. The correct capatance across the primary eliminates all blinking and the little hand is no longer needed.

There is very little improvement when the power goes up in the morning.

What it is:

Secondary - 20 turn coil of 14 gauge wrapped according to EPD. With attention to getting the coil to the proper EPD dimensions. So spacing was what it was.

Primary - Almost 2 turns of Stout Flat copper.
84.5mm wide
2857.5mm long(10mm short) Best I Could Do. Now I need to shorten the Secondary
1.35mm thick (STOUT)

I made this from a 1.25"dia copper pipe. Split it lenght wise on a table saw. Hammered an ax down the lenght to open it up. Used pliers to open one end wide enough to get it in a sheet metal roller and rolled it flat in 12 passes.

FWBR - Of 1N34 diodes across the secondary or from almost any point on the secondary to bottom of secondary.

LED - across the DC of the FWBR.

Ground or antenna? - Bottom of secondary is connected to Fireplace shroud/metal chimney. It is grounded via propane copper tubing but it also acts like an antenna since its big metal and sticks out the roof.

coments and questions are welcome.

Congratulations. Thanks for the report and photo. Is your only antenna the short wire on top of the primary coil (or are you connecting to an external antenna wire in addition to the fireplace ground)? Please post a link to the page where you got the EPD info.

@ jake

Replacing LED with a capacitor and then using capacitor as a battery for Joule thief circuit should produce brighter LED. You must be getting at least 2 volts out of FWR in order to light the LED so you should have no problem driving a low current Joule thief circuit.

http://www.energeticforum.com/179223-post956.html

First four equations are the most important as far as I can tell. (wire length, turn length, coil diameter, coil hight) Primary width is 18% of coil diameter but I cant find the post. It's somewhere on the "Peter what happened to Eric" thread, search the T-Rex posts. If you can figure out how to incorporate the other items into your build without loosing the first 4 the the better according to EPD. Not having the correct size tube, I used 14 gauge as recommended by Eric. Coax is also recommended by Eric but I felt this was a compromise to another extream, so I went with the 14 gauge solid.

There are a few excell calculators on the yahoo group. I wrote the TRTcalc3.xls. These will do the math for you. If you are not a member PM me and I will send it to you. We cant post excel files here. Now that I think about it I should update that spreadsheet again.

As you know from you exciter experience there are variables in designing a coil. This way, adds a few more variables in the mix. This coil is based on a few ideas EPD described in his writings and old school HAM techniques, brought back to life by EPD. Spaced windings, active copper volume match
and Erics formule were a few of my considerations.

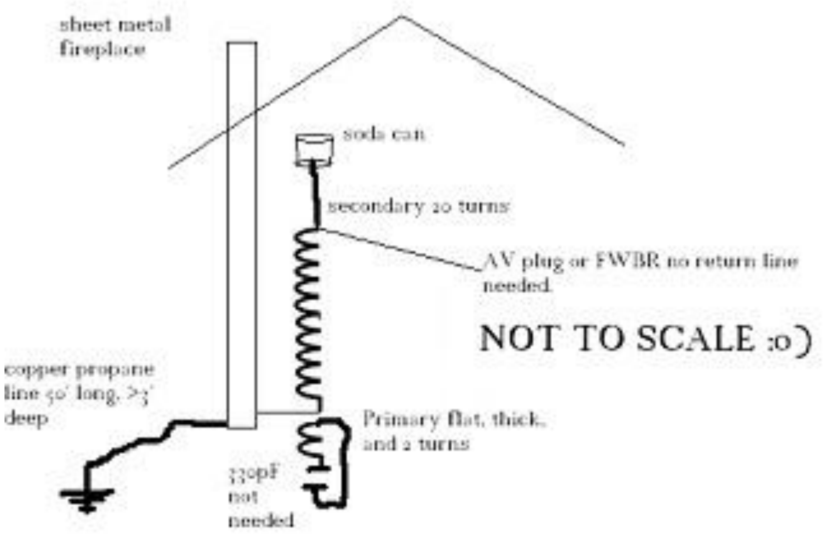
The extra coil is still a bit of a mystery. I am not using one. I made one but I have not figured out what it is supposed to do, and how it does it. Erics dimensions were tenetive(as he described) at best and not all the equations make sense to me at least. I am almost ready to revisit that.

ALSO I got an LED AV plug to glow just as well as the FWBR. One wire to the top of the secondary and another lead off the negative of the LED laying on the tile.

The fireplace is metal and sticks out of the roof so its like an antenna. but its grounded so I dont know what to call it.

EDIT:!!!
OK fireplace not needed!!!

I connected to the mains ground and adjusted the CAN, now the LED is on, bottom of the secondary is mains ground and soda can antenna.



sheet metal fireplace
soda can
secondary 20 turns
AV plug or FWBR no return line needed.
NOT TO SCALE :o)
copper propane line 50' long, >3' deep
Primary flat, thick, and 2 turns
330pF not needed

This is the theory for the crystal set initative AND an appropriate experiment for validation. To my knowledge it has not been accomplished. It is based on the following post.

http://www.energeticforum.com/renewa...tml#post173955

Quote:

Dry sand or rock will not ground, so this requires 80, each 14 gauge wires in a 30 foot diameter circle in a star radial configuration, to a center terminal. Without these groundings a Tesla Transformer cannot properly operate, but some "HI-Z" sets may.*
>
> *The objective here is to scale the "Crystal Set", a step at a time, into a Tesla Transformer for the reception of medium wave band, 300 - 3000 kilocycle A.M. broadcasts. No license is required for this and the broadcast station provides the power.*
>
> *And this objective cooperates with the primary objective. That is; Who will be the first ham to disprove Einstein's theory? An International contest, but who will sponsor it, Iran maybe?*
>
> *We have the good fortune in the "Crystal Set Initiative" that, in theory at least, a quarter wave A.M. broadcast tower, and its 120 quarter wave ground radials, must emit a pair of waves as shown by Tesla in his basic diagrams.*
>
> *Hence it can be seen that a pair of waves are engendered by this transmission system. (Tower*

> *and Star Radials). One wave, Hertzian, is the over ground wave, the other wave, Telluric, is the under ground wave. These two waves arrive at the point of reception in their own distinct time frames, giving rise to a difference in phase. Hence, multiple rings of interference patterns are produced. Since the Hertzian portion, over ground, time frame is based upon the velocity of light, then the Telluric portion, under ground, time frame gives the Telluric velocity. Two crystal sets, one over ground, one under ground, and a basic oscilloscope , that simple. I have done this at Landers.*
>
> *Concluding, a Tesla Magnification Transformer, properly proportioned can, in theory, actually draw power from a local 50 kW station. Several hundred watts of power reception is likely. This would prove Tesla once and for all. No antenna, just a good ground, and a nice and bright 100 watt light bulb.*
>
> *This would overturn physics more than any billion dollar C.E.R.N. project. A ham radio operator overturns Einstein for 100 bucks. What a concept.*

Some more build info form the "Peter where's Eric" thread that was locked.

I wonder if Aaron could sticky it to the begining of the EPD thread.

> *The design of the Tesla Transformer starts with the secondary resonant coil. In its resonant mode it is a quadrapolar resonator. Two constants exist in the construction of this solenoidal resonator, one is that the height to length ratio must be 20%, the other is that the side by side spacing of the cylindrical conductor turns is 62% the diameter of the cylindrical conductor. The optimum number of turns is 20 on the secondary, with 2 on the primary. This gives the physical size of the coil for a given frequency. Increasing the number of turns reduces the size of the secondary coil in proportion to the increase in turns. Accordingly the conductor diameter also decreases as the copper is spread out over more windings. The ratio of secondary turns to primary turns must equal a constraint of 10 to 1. For a given number of*

> *turns the operating frequency becomes the sole independent variable in coil design.*
>
> *The primary coil is the same diameter as the secondary coil. The ratio of conductor width to coil diameter is 18%. The sheet conductor is closely spiralled into two turns, for a secondary of twenty turns. For a conductor thickness as given by the maximum thickness vs frequency the volume of the primary metal must equal the volume of the secondary metal, based upon equal weights for primary and secondary metals. Brass can be 1.7 times thicker than copper, and bronze can be 2.8 times thicker than copper, for a given maximum thickness and frequency.*
>
> *The primary condenser should be made of the same amount of metal as the primary coil. Their weights should be about the same. The connecting leads must be short and the same width as the primary conductor. Large, multiplate air condensers are good, so are metal sheets and glass.*
>
> *The secondary capacitance is best a copper tubing ring around the outside of the H end of the coil. This ring must be open in one spot along its loop so as not to be a shorted turn. The end of the secondary wire connects to this capacity ring. Beer cans make the best elevated capacitors.*
>
> *The finished transformer must operate on a directly connected ground plane. A large plywood table with aluminum foil glued on to it, this covered with a plastic or glass sheet is the minimum required ground plane. Obviously the aluminum plane must be solidly earthed with special attention to minimizing ground lead inductance. In order to light a lamp a more broadcast station style of ground plane is required, but for testing purposes the metallized plywood "ten by" sheet is just fine. Good luck and good crystal set DX ing.*

There is no step by step guide to tuning this. Following basic DX, crystal set rules do not necessary apply IMHO.

All the theory is in here: [http://www.energeticforum.com/renewa...tml#post15858]

I do not want to talk about theory of operation here. Just observations and diffferences between this design and a normal crystal set design. For an unbiased Theory pull out the T-rex posts from the above thread and read. Not that there is not other great information in that thread but it can make you mind wander. Read the other posts after you determine if you understand Eric or not. I found page 26 a great place to start. Lots of good T-rex posts before that but they are a bit advanced and its hard to apply to those lessons before you understand the basics and that is what this is about.

Learning the basics.

RF Probe

For those who may not have RF test gear, I found a simple RF circuit you can make to read RF voltages on a DMM.

N5ESE's Classic RF Probe

I made one this afternoon took about 30mins, used an aluminum cigar tube for the RF shielded body.

The AV plug appears to not have a return, but it actually does. The return path is through capacitive coupling. There is always some amount of capacitive coupling between any two conductors. Touching one side of the LED will increase the capacitance since that allows the high frequency current to flow over the surface of your body and increases the area of the capacitive plate. Normally this requires higher voltage than you have in order to work wirelessly so I am surprised that you can get it to work without a return wire with the voltage you have. The circuit is just a diode rectifier feeding an LED. The diodes prevent the reverse voltage across the LED from getting high enough to burn it out (LEDs can only have about 10 volts of reverse voltage before they will be destroyed).

That is perfect! But wait lets make it better.

I don't care about accuracy. I want maximum sensitivity and stability so I can tell where the peak is. Becides ditching the the resistor should I consider another sized cap? 0.01uF seems a little large for use on a crystal set

@ all,

When using 0.5v PP on the function generator(lowest setting) across 1 turn of the primary I can use an AV plug to trace the secondary and "see" the high and low points along the entire secondary. Middle 5 turns have close to nothing. All the umph is at the top and bottom of the secondary.

Now to get that umph into the extra coil through the cap without loosing anything.

@ jake

I calculated the field strength voltage 5 miles away from a 1,000 watt transmitter to be 0.03 volts per meter. This is a rough calculation but gives approximate value to be expected. You are getting much more out. I am impressed with your design. I worked several years as an antenna engineer developing very advanced antenna designs, so it takes a bit to impress me.

For a 10,000 watt transmitter this increases to about 0.10 volts per meter.

After I did the calculations the hard way, I found an online calculator that gives about the same answers:

Volt per meter and power density calculator

EDIT: A tuned antenna will suck up the RF energy much like an electronic vacuum cleaner, so I would expect your antenna to produce more than the ambient volts. It is actually possible to measure the lack of signal behind a tuned antenna which shows it has absorbed energy from an area much larger than itself.

xee2 you rock

The funny thing is: The coil responds best when excited at ~2200kHz. So I may be getting signal from another station but I cant hear it because 1620 is so loud.

What cap? There is no reason to go over 100 pf for coupling at 1 MHz. The smaller the coupling cap is the higher the resonator Q will be.

No. If you are hearing 1620 then that is where the power is coming from. You will hear the station delivering the most power.

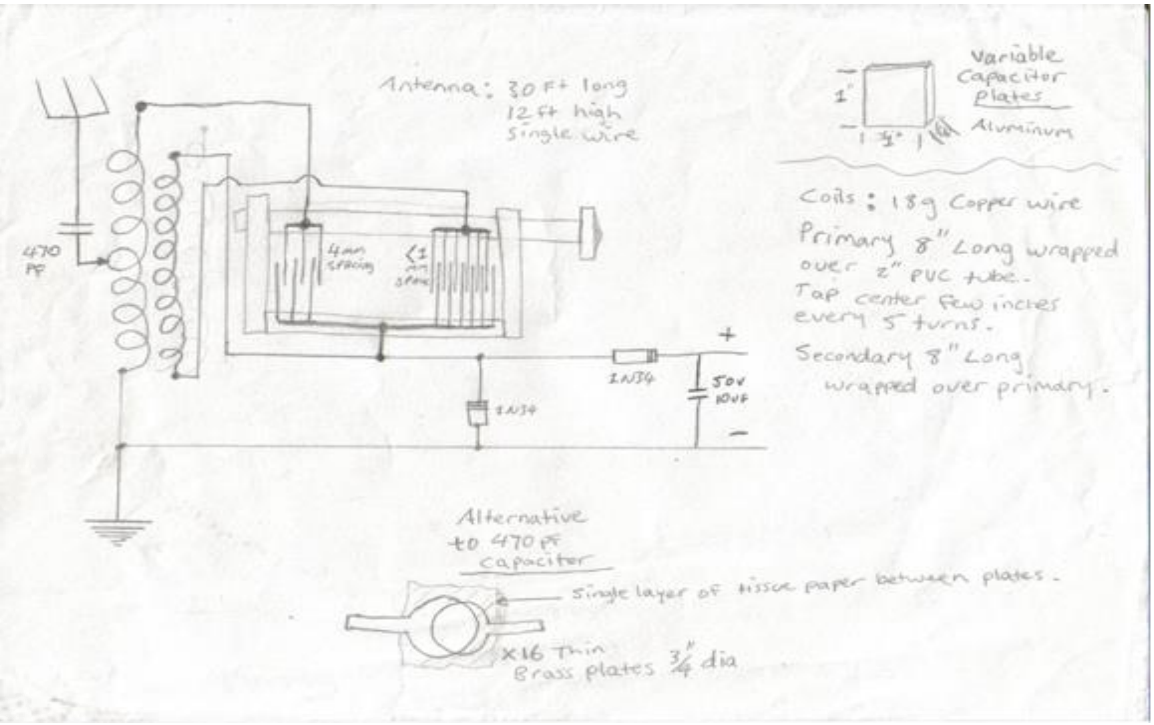
Hi Jake....nice work.

Thought i'd post my setup here for you.
I'm getting 25+ volts from my circuit and i can run a wall clock from it very well.
I made my own 2 gang vari cap from some bits of aluminium glued to a wooden dowel.
I'm using about 30 feet of data cable as antenna but anything works...even just an iron wire....
My antenna is about 12 to 15 feet in the air.
My coil is tuned to 774 khz but i also get 1550 khz as well.
The 774 station is about 20 kilometers away from me, and i think it is a 50,000 w transmitter....i think?
Here is a link showing my setup running a clock.
[clock radio - YouTube]

I wind the primary with taps, then i just wind the secondary straight over the primary.
I'd like to see someone else try this setup and see how it performs.
Cheers.
Scotty.



Antenna: 30 Ft long
12 ft high
Single wire
470 PF
4mm spacing
<1 mm space
1N34
1N34
50v 10uF
+
-
Variable Capacitor plates
1"
1 ½"
Aluminum
Coils: 18g Copper wire
Primary 8" Long wrapped over 2" PVC tube.
Tap center few inches every 5 turns.
Secondary 8" Long wrapped over primary.
Alternative to 470 pF capacitor
Single layer of tissue paper between plates.
X16 Thin Brass plates ¾" dia

Standing/Stationary "wave"

@ all: Does this make sense?? Is this normal antenna theory stuff?

I am using bare 14gauge wire. So I can tap it at any point, and I do. There is a standing/stationary wave along the entire coil when excited at ~2200kHz. Max voltage is on the soda can, and again max at the bottom of the secondary by the grounding at ~2200kHz. With an area in the center of tht gives no readings. In this case I am feeding it with a function generator.

When attached to my magic "fireplace gouund " I get hightest signal close to the top of the secondary but not on the can and the voltage does not go up at the bottom.

This tells me I need more interwinding capacitance or a capacitor across or the split ring the secondary think
I think it's time for me to learn YouTube. I'm a video posting virgin. But the standing wave visual is cool.

And finally, my detector is an AV plug with germanium diodes. Crystal ear phone is attached across the LED and I can hear the station and the light glows when I tap points. This is the on the unpowered setup. Better yet I can hear the station on the "AV LED-head piece" 1" away from the secondary without touching, and it gets louder the closer you get.

Which means I am radiating. Which is bad.

So is this normal stuff?

@ loadstone

NICE!

Wish I had seen that earlier. Tried earlier on to get a joule thief to work but failed. Then I got good light from the coil directly and dropped that idea. I'm borrowing a function generator so I'm spending my time working with that. I'll eventually get a thief to steal radiowaves.

Did you ever work with 1N34 germanium diodes? How do thay compare to the ones in the video?

@ Jake....i have used 1N34's but in my clip they are a different type...i think 1n60.....
I started off getting low voltages and refined it until i can get up to 28 volts out @ 500 ua.....not much power but i can run various small devices or charge batteries now.
It's all fun....i also tinker with the capacity versus inductance ect....teaches you alot!
Scotty.

Just noticed this edit:

Right now it does nothing to a radio when I plug hook up the secondary but I can still light the led.

One previous setup it was making the radio louder when I hooked it up. I think it was when I grounded it to the house ground but the led would just fliker every once in a while.

This is where the extra coil and ring capacitor come in to play. I dont want to change the wire length, coil hight or coil diameter. So all I have is capacitance and I have tried: a 3 turn 505pf variable air cap. A 112pf HV air cap. and a couple of other crystal radio/pocket radio caps and they just dont do much of anything across the secondary.

The crystal radio project is to recover Teluric currents, not hertzian waves. This is why ground is THE most important part of the project.

recovering hertzian waves and magnifying them to power LED's etc.. is nothing new, novel but not what Eric was going for.

Diodes, 1N34A have a very low FW voltage, and a high 50V breakdown. 1N60 is nearly twice as high in forward voltage with a lower 40v breakdown, although the 1N60 is supposedly mfg to higher tolerances.

a ground impedance of 1ohm or less is going to be the biggest and for most an impossible requirement.

Yes, you are correct. However one can use the Hertzian waves to tune their secondary, just like we are doing with the function generator. LEDs make pretty good HF indicator lights.

So whats you take on my standing wave question? last page

Not sure I understand what you're after, could you explain a bit more?

Also this is going to be frustrating, but all leads will impact the L&C of the circuit, I found that by using the coil itself it's a better compramise then adding in wire length. the leads and LED also effect the circuit too, it's a big balance game.

Yes, Yes, and Yes I noticed that.

A wise man once said "we were going to need a new set of tools to work with these new concepts" or something along those lines. Once I realized I could easily light an led I thought that it could make a handy dandy indicator. THEN..

I get my hands on a 10MHz function generator. I start testing and messing but lacking a fuctional ground I can only take my results as mere observations of a crystal radio and NOT a TRT. What did I learn....that leads are the enemy. Thats when I made the leap form FWBR to AV plug and that made all the difference. Thanks to all those who helped with that. No leads and 1 point of contact. That makes a nice little indicator. With that indicator I can touch the coil at any point. And it appears to make very little change to the resonant frequency. The change I do see is usually caused by me holding the AV plug. BUT I cant get the AV plut to light on a stick.!

I'm going to be a bit lazy here and point you to this, Standing waves and resonance : TRANSMISSION LINES it may help answer some questions, if you've got more after, let me know.

the length, are you referring to the physical wire length or the length of the coil? there is also the issue of electrical length. gets more involved with RF and transmission, esp here since C is no longer a fixed value.

For parallel resonator or self resonant coil:
When the resonator is at resonance there will be a standing wave on the inductor wire with a peak voltage measured across the ends. Note that this is an RF wave not DC. Best way to measure this is with scope using very small capacitor as probe. There will be multiple peaks if the resonator is resonating at a harmonic of fundamental resonator frequency.

Oooops!!!

So I went outside soldered into a ground wire and set to work. With 1 turn, 1/2" flat copper stock primary. Tried different arials, different hights, and so on and so on. Got it down to 1620(heard it on the radio 15' away) with a big aluminum salad bowl. , I went back to no terminal and put on my big fat 2 turn primary. Started testing with this when

A small white exlporer sticker on side said "Texas Communicat........." Could not read the whole thing. Pulled into my driveway waved nicely at me then drove off nice and slow....

There is a company called "Texas Communications" that runs communication services and it may have been one of their trucks. but still It did not feel right.

Did I break a rule?? FCC or other??

Function Generator signal level never went past 1/3. and was usually all the way down..

BK Precision 4017A, 10mHz, 10v(max) p-p into 50ohm, minium .25v p-p across my scope.

I doubt that your signal generator will put out enough power to interfere with anything unless you have neighbors within a 100 feet and then they would need to have a radio tuned to the frequency you are using (unlikely).

The FCC has no sense of humor, be careful.
wiki link on FCC broadcasting regs
Title 47 CFR Part 15 - Wikipedia, the free encyclopedia

20dBm = 100mW is the maximum allowed, also there is limits on antennae length. ground and above ground total to 3meters.

Im Back!

So before I was freaked out earlier. I was tring to figure out the standing issue I have.
@ mad, I like it when you lazy.

So what I really wanted to ask was why is there only a partial wave along the coil at resonance? With a 1 turn primary I get 1/4 of a wave along the entire coil. Meaning the the can has highest "potential and the potential along the coductor goes down to nothing as you approach ground.

However a few days ago I had 1/2 wave at resonance when I was using my primary instead of a 1 turn copper strip. Meaning highest potential on terminal, the 5 turns on in the middle of the coil had nothing and voltage went back up(actually -) as you approached the ground.

I had just got my primary back on when. I pooped my pants.. Spent the rest of the day at FCC.. and wiki.

What did I learn there: 2mHz-3.5mHz is wierd and is allocated to maritime, ship to shore, and other , but the coast guard uses it as well and I can't forget 2.1735MHz mobile distress and calling frequency.. I was all over that one today. With the right termination/salad bowl. I learned I can keep it under 2MHz and still play as long as I keep it turned down all the way..

I used a FWBR made from SF35s and SF37s diodes. Across the DC of the FWBR I used a 100pF cap. Powering the function generator at 1.8MHz the max I could get was 90mA straight across a DMM out from the rectifier. How do I go from that to "milliwatts of DC input power to the final RF stage"?

time to do the pots.

You must have had a bad ground connection. Ground should never have a voltage on it (it is the reference for all other voltages).

You need to measure imput impedance of antenna to determine how much power is going into it. But it will look like like a small capacitor. To get power into the antenna you need to make a matching network to convert generator impedance to complex conjugate of antenna impedance. As is, 90% of power appllied to your wire antenna is being reflected back to generator (less than 10% is going into antenna). So the amount of power your antenna is readiating is very small.

Awesome.. Thats why I went outside and soldered directly to decent "ground". Did not stay out long enough to prove it to myself.

I was hoping for more answers like this...

BUT what the #?*! did you just say..

I never wanted to transmit.. never planned on it.. still dont want to. I'm more of a receiver.

Is "very small" enough to make a radio 15' away scream like a banchee. By scream like a banchee I mean, completely drown out the local station that was coming in loud and clear? And boost the volume?

I have absolutely no reference of radiated RF and its capabilities. So I appreciate the replies.

At 15 feet you are coupling to the receiver directly not picking up the RF radiation. A wavelength at 1 MHz is 1000 feet so 15 feet is only a few percent of a wavelength away. This is called near field coupling and is very strong.

It is hard to tell from diagram. I was assuming you were just connecting a wire to signal generator. In this case there is a whole circuit attached. But I suspect that most of the energy is being reflected back into the generator. Getting an electrically small antenna (length only a small fraction of a wavelength) to radiate all of the power being fed to it requires much work. When the length gets to be 1/4 wavelength the antenna impedance will be close enough to 50 ohms to radiate most of power. But less than than 1/4 wavelength will reflect most of the power fed to it from a 50 ohm source.

If you are tuning with the set up in diagram, be aware that the frequency is going to be effected by the loop attached to the generator. I think it would be better to use a short wire well away from the receiver resonator to transmit with when tuning the resonator.

Being close to the resonator will also effect tuning. I recommend sweeping the frequency to see where it resonates, adjust, move away, sweep frequency to see where it is resonant, ... etc.

-1 turn primary flat 1/2". in series across the Function generator
-20 turn secondary 29.5-30.0 meters. about 2" above the secondary, same diameter
-Coil was most active at 2000kcycles. It lit an av plug the brightest at the greatest distance.

Considering these three observations, and considering the 20 turn secondary as the antenna;

Can I conclude the coil is acting like a (1/4 lamda) 150m antenna? (i.e. I have electrically lengthened the 30m wire I used in the secondary)

It is possible but there is no way for me to tell if that is happening. But the resonant frequency is going to change when you disconnect the generator if the generator is tightly coupled to the resonator. I think your objective is to get the receiver tuned to the correct frequency, not to make a transmitter tuned to the correct frequency.

You are correct

and on the way there I'm disecting each component.

I do not know what frequency the secondary should resonate as it is shown in the diagram. What part the secondary plays in the TRT I do not know. I think Eric may be the only one. But this is not a TRT, just yet.

So I am looking at the coil from all angles. How it was a radiator in this case study, not exactly what I was expecting but Ill take what I can get.

When excited @ 2000kcycles it radiates quite readily but at 1620 not so well . Same goes for receiving I thought...

'CAN' or Beer can/ dr pepper can, is the standard end termination for the Crystal Radio Initative. Dollard recommended it and I think those building are also using it in testing.

I need a lot of 'CAN' to bring it down to 1620. But how much 'CAN' will be provided by the extra coil, I do not know. The two split rings in the final design of the TRT will allow for some adjustment. Of 'what' is still to be determined. So much I do not know.

As far as the 150m question I was just trying to figure out why it ended up that way since I was only using 30m of wire. But I think I got that part figured out.

@ jake

Wow, that looks complicated.

To lower your frequency you need to add parallel capacitance to the coil. Probably about 5 to 10 pF. You can make an adjustable capacitor with two sheets of copper overlapped with insulator in between and held together with a clothes pin.

20kv nice

I played around with HV a lot last year. 50uF spark discharges of up to 5000V. Neon sign transformers and spark gaps are fun. I could light neons 15' away when stuck into the ground. The whole plastic as conductor also worked with NSTs.

I also did 3 Henry discharges/oscillations. Only 24v but scary with the amps I knew were there. I melted 4 neons in parallel this way. It only took 12 volts to melt 1 neon.

Any following Tesla's advice I went with smaller and smaller caps and faster and faster frequencies. That is when Eric came out with the crystal initiative and I thought that would be a good way to learn the in and outs of HF.

As I proceed I am trying to figure out what is HF related and what is HV related. I am so used to working with and reading about HF/HV at the same time I forgot that they are each their own entity.

I am starting to like this HF stuff.

@madhatter,

What causes the two small peaks on each side of the large resonant point? I don't have a scope but they "show" up as audio on the piezo. It lets me know I'm getting close.

it may have to do with the phase shift, before resonance the current leads the voltage at resonance it is in phase and after the current lags the emf. The shift may be what you're picking up.

I am not sure what your setup is so this is hard to answer. But it is probably the modulation on the carrier. This shows up as sidebands in the frequency domain. You can sometimes even see this from signal generators due to 60 Hz leakage.

Smokey - Introduction

Hello All,
Here to introduce myself and have an Extra Coil discovery that you all need to know about which I will post shortly.
Have been over at 'n6kph' and working with, David, Jake, Scott and Gary Peterson of 'TFCBooks' and all have been most helpful.
This introduction is a copy of one I made at n6kph in response to a Post:

Gary,
These tests of Erics are designed to gain some distance tuning knowledge with the Extra Coil and with the Secondary test, to tune in the local AM Station via the Hertzian component and not the Telluric.

I have four Oscilloscopes, 1 x 100 Mhz (HP 1741A), 2 x Tektronix Valve and a Telequipment solid state which is UK Tektronix.
Have a fully set up Lab that has basically taken me 10 years to acquire or build the required tools.
Only thing I don't have is a Spectrum Analyser and working on that now.
Am not a Ham but fully qualified to be so and have a considerable collection of Vacuum Tubes that go along with my research, Moray/Ion Valve/Smith/Kapanadze type research.
I am 70 years of age and been at this full time since retiring 10 years ago.
I am ex Radio Station, RANavy, NASA Tidbinbilla Space Track and finally electronic designing for the Auto Industry.
Repairing a Yaesu FT-901 Transceiver due to its AM driver capabilities ready for the next step but these initial problems need to be overcome with respect to design.
Yes, I have seen your repeated information but can only do one step at a time and will get to do your Oscilloscope tests at the right time which is not right now as the working data is suspect as is my Extra Coil.
I am also into Aetheric Weather Engineering after Wilhelm Reich and TJ Constable etc which is another story again but helps with the Aetheric ubderstanding associated with all of this.
I have 13 devices here that can make it rain and all of which are not recognised by 'science' just as is Tesla's TMT and why I am also following this path.
Letting you know where I come from.

Extra Coil Math Discovery

This Post is repeated at 'n6kph'.

A Discovery - Extra Coil:
I find repeatedly that simple Maths is a significant part of discovery and has allowed me to build many devices that others have failed at or not even bothered with, all because it appeared too hard.
I now have two Extra Coils, one considered wrong Math and the newer considered the correct Math.
Question to me was that the old worked and the new doesn't but why?
You may remember me saying that my first attempt at this coil worked as I was picking up my local 2 Kw station with the Headphone capacitor antenna some 8 to 10" away from the Extra Coil and it was proven to be a Telluric signal and not Hertzian.

The Math:
Old Coil data - works:
CalcF = 1.557 Mhz (1.557 x pi/2 = 2.4457) MULTIPLY
53 turns of 14 awg (same as Secondary wire size) with a diameter of 195.2mm
L = 30.829 meters (9.7244 Mhz)
Actual 1/4 wave Fres = 2.4655 Mhz AFTER F 1.557 Mhz
Error long by 198 Hz which means I need more turns over the 53 I did have but probably only one required and this should increase signal strength as well.

New Coil data - doesn't work:
Calc F = 1.557 Mhz (1.557 / pi/2 = 991.2 Khz) DIVIDE
125 turns of 21 awg with diameter of 195.2mm.
L = 75.61 meters (3.965 Mhz)
Actual 1/4 wave Fres = 991.4 Khz BEFORE F 1.557 Mhz

What this is saying is that you need to find the 1/4 Wave point from your number of turns and that needs to match your signal frequency MULTIPLIED by pi/2. (1.557 x (pi/2) = 2.4457 Mhz)

When I had completed the first coil I was happy with the Math and why I went ahead with the build.
It is only now, on analysis that the Math can be presented on paper and you can see what is happening here.
What I first built was, I feel, correct as the pi component is at the correct point AFTER the centre point going on to the full 1/4 wave and not before the 1/8th wave point.
This AFTER point is where Tesla's 'standing wave' is permitted/allowed to occur.
The second coil has its pi point BEFORE the 1/8 wave point and cannot resonate correctly and will be difficult to tune as is noted in the documentation many times.
What is of significance here is exactly where the pi point is (where your reference signal is) and is not a harmonic or octave or any of the regular resonance points but WITHIN THE FULL QUARTER WAVE at the 1/4 wave/pi/2 point and this is where your reference signal is located. (2.4457/(pi/2) = 1.557 Mhz)

If your Extra Coil does not work or is difficult to tune then the above will explain why.
If you then build a new Coil to the guide above, you will meet with guaranteed success as proven above.

I now have a difficult challenge to figure out if Tesla was on the wrong side with his pi point and working on that now.
I will be building a new coil on a new more open frame but adding one more turn to home in on the exact point as I still have the original wire ready to rewind.
Will advise as I proceed.
Hope you can understand what is documented above.
You MUST know your simple Maths if you are ever going to succeed in this business as I relate from empirical experience.
Good luck with your builds.
Will introduce myself over at Energetic and present this document as well.
Thanks.

Smokey

PS:
If anybody can see an obvious piece of data that I have overlooked, please respond.
David,
Would like to hear Eric's comments on this 'discovery'
Thanks.

> *Would like to hear Eric's comments on this 'discovery'*
> *Thanks.*

Smokey,

I like the Energetic Forum 'style' so I will ask questions here. Also, Eric is more apt to see info posted on the forum and *not* the Yahoo group since he doesn't know how to navigate it. Discussion here in the open is going to preserve these conversations *on one thread* for Eric to see since there is no way I can remember all details that he might like to know. How did you arrive at your calculations? I only briefly looked but couldn't find how you got a calculated frequency of 1.557 MHz.

That being said, if you can present your findings in a manner that builds them up from Eric's initial design equations to where your experiments have taken you, I will refer Eric to this thread. He told me the other day that he wanted to check the forum again to see if there has been any activity so he is looking for somebody with a computer to use.

Geometric_Algebra has been the only one to be able to functionally correspond with Eric thru the postal service. Eric received a letter from Geometric_Algebra that included coil dimensions, measurements, errors, etc. and sent back a response that is on the Eric P. Dollard thread. If you send Eric something that is a worthwhile question, he will respond. However, since you seem to be on the other side of the world, you should document your results here on this forum either in this thread or Eric's thread so that you are using a medium that Eric is used to.

I would be more than willing to use my own printer and paper to get questions to Eric for everybody that doesn't have convenient access the the United States Postal Service. However, I have no money and my printer is out of ink. If somebody wants to help with these problems, I will print and mail all day long. Otherwise, hope that Eric can have access to the forum long enough to fully digest your post or you'll have to mail him from your location.

Sorry about the inconveniences,

Dave

Extra Coil Confirmation

Confirmation:
Here is the Tesla data based on the Colorado Spring's Notes:
Extra Diameter = 2.52m
One Turn 2pir = 7.9168m
Turns = 100 Total Length = 791.7m
Full Wave = 378.67 Khz
1/4 Wave = 94.6675 Khz
Operating Signal Point 94.6675 MULTIPLY pi/2 = 148.703 Khz
Where Tesla should have been working and NOT here:
94.6675 DIVIDE pi/2 = 60.267 Khz where he was working and supported in the CS Notes 'about 59 Khz'.

Think this is sufficient evidence to point to the base reason why the Extra Coil is so hard to tune and is very much not so at the AFTER and not BEFORE 1/8 Wave point.
It may have been difficult for Tesla to get to the higher frequency where he should and probably knew he should be working at and this is his compromise.
He may have also considered that what he was attempting to achieve would work from both sides and chose the DIVIDE path when he should have gone the MULTIPLY way.
Hope this makes it clear as to what is required with your Extra Coil to make it work.

Am satisfied now that this is the case and will rebuild my Extra Coil to the new dimensions which will be:
F = 1.557 Mhz MULTIPLY (pi/2) = 2.4457 Mhz = 1/4 Wave.
Full wave = 9.78292 Mhz = 30.644 meters
Diameter = 195.2mm (r = 97.6 mm)
1 Turn = 2pir = 613.23 mm
Number of Turns = 30644/613.23 = 49.97
Wire size, same as Secondary and 14 awg in my case.
Number of turns very close to my original figure of 53 but would suggest that you add about 5 extra turns and then trim or better to probe back on turns that you have cleared of insulation when you can get a Sig Gen set on the exact frequency of your station and then tune for maximum gain in the Headphones or on the Intensity meter.
Hope this explanation is now clear to everyone.

Will be honest and say that using 21 awg for the new Extra did not appear correct as I could not see being able to pump this frail device with any watts to achieve a goal.
This IS different!
Will now go build my new Extra Coil and make this fact for good as it has already been proven by empirical means.
I have Tesla nodding approval.
Thanks.

Radio Station Frequency

David,

The 1.557 Mhz is my local Radio Station that I am tuning into.
If you follow my last Post it is fully exampled there and shows what I feel Tesla would like to have done but couldn't due to technical shortages of his equipment or he may have just gone the wrong way.

Wish I could help more from afar but not easy - I have 5 Computers here, all the old ones I have fixed their problems and sit here unused or just kept as data monitors.

Think this IS a significant discovery and just needs builders to first understand what I have proposed and then to build following my examples.
The important issue here is where your AM Radio Station sits in the 1/4 Wave and needs to be at the 0.637 point of the 1/4 Wave of your Coil.
From my previous example - 1.557/2.4457 = 0.637 or on the HIGH side of your local AM Radio Station signal
I will now go away and work on what that point is, as it must have some other significance besides pi.
The Tesla way was 1.557/991.2 = 1.5708 or better as a comparison 991.2/1.557 = 0.637 the same but on the LOWER side of your Radio signal.

I knew 0.637 was something to do with AC and here is the connection:

Measuring the Sine Wave

The Average value of a Sine Wave.
Note now the association here with pi and the average value of a Sine or AC wave and this in itself speaks volumes.
This is where the 'magnification' takes place.
Now that we have a 'something' to work with we may be able to make some considerable steps in evolving this Free Enegy that we seek in all of our Coil designs.
Hope you have all been able to follow this unravelling so to speak as it just simply now makes all that much sense.
I have a Coil to build.

As a side note, please note that I have been at Energetic since March 2008 sitting on the sidelines and waitimg for my moment.
Hopefully it has arrived.

some fun with math.
300,000,000 x Pi/2 = 300,000,000 x 1.5707 = 471,238,898.04
300,000,000/471,238,898.04 = 0.636619772
1/(Pi/2) = 0.636619772
2/Pi = 0.636619772
0.636619772 x (2 x Pi) "revolution" = 4 "radians"

Not fun.

So it comes down to "A/(A*Pi/2)=0.63661977"

@ David G Dawson

Have you built an antenna using the same EPD design that Jake is using? If so how well does it work?

why not fun?

I think you mean, 'A/(A(Pi/2)=0.636619772'

What I was getting at was that 0.6366.... is a function of Trig. As Smokey mentioned the A/C useage it's the rms multiplier value for 1/2 of the sine wave of a rectified wave for DC. and .707 is the full wave. a lot of these 'numbers' will factor back out and can seem 'magical', they do help in recognizing patterns and relations though.

That's why I thought you chose 1.557 Mhz. I can get lucky sometimes Good to see you here Smokey! I've been on Bruce Perreault's list for something like 15 years and have seen you there as well as the OU forum. Always enjoy your posts. While I've built crystal radio's long ago I'm not really up to speed on this thread. Would you say your concept is anything like a scalar energy receiver?

Extra Coil detail

Quote:

Yes, and it doesn't work.
My old design as per my instructions worked first off without any problems and was picking up the signal from the 1N34 probe head into high impedance Headphones from 8 to 10 " away from

the Extra and this was on a piece of metal used as a neutralising capacitor in an old RF transmitter without any specific direction of alignment.
It was obvious that the coil was radiating as well as magnifying the signal and was of a Telluric nature.
It is very clear in Tesla's Colorado Springs Notes that the length of the Secondary be equal to the Extra and this is NOT the case in Eric/Jake's example but is in mine.
I will put up some pics of both so you can see what I am talking about.

Just getting used to the procedures here at Energetic and always thought it was a neat means of display and communication.

Busy day here building the 3rd Coil but will come back later and put my formula into a step by step instruction so that it can be easily followed.
I am/was most familiar with spreadsheets but will leave that to the keen ones like Jake if he would like to build a new sheet for this working proposal at some later date after I have the 3rd coil working.

The final Colorado Spring's organisation only had 17 turns on the Secondary but I am using 20 as instructed but have a tap at 17 for testing purposes.
I, like Eric, spent many hours digesting the CSNotes and have come away with a different theory than Eric which works.
Eric leaves me for dead with the engineering data side but I have intuition on my side which has worked very well in the past.
Thinking about my working theory and I need to progress on that from an engineering viewpoint.

I have spelt it all out in the Posts but may be difficult to follow.
No, Phi is not involved here so far as no connection has been found.

On the new coil I will allow for fine tuning for a peak as the last one was just as built and could probably have been improved considerably and will fit this stage into the final Math.
Currently reading Eric's 'The Tesla Transformer' and can see some new holes there that need filling.
Later on this.

Thanks for the reply. For your information, you can post images here but the storage space is very small so it will fill up quick. This is probably best to start with. But you will need to use ImageShack® - Online Photo and Video Hosting and paste the link into your post here when your space is filled up. They now require setting up an account. Setting image size to 640x480 or 800x600 will fit on screen best. There is a preview button that allows you to check how your post will look before actually submitting the post.

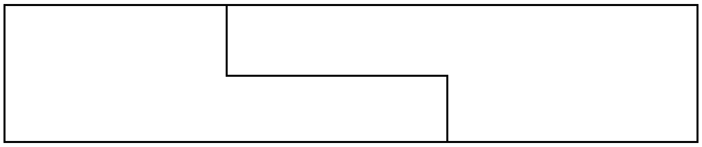
Whats going to happen next?

I got my hands on a piece of copper flashing 59" x 7". That is about as good as it gets for me. Right size, Right volume, or close enough to start. This will be my primary capacitor and connecting lengths. My thought is a simple two plate capacitor.

cut it like this.. and the thinner strips solder to the primary.



By jastermake at 2012-04-30

BUT, before I cut...

What will the 2 turn primary and capacitor do to the resonant frequency of the secondary when I excite them both? I'll be using the same 1 turn strip and function generator I used to test the secondary?

What else should I consider when designing this capacitor? Please keep in mind this capacitor may play more than one role in this setup. I believe Eric called this capacitor the 'energy transformer' in one video.

So.... what will it do?

Jan 2, 1900:

New Extra coil, 98 turns last modification.

25' 11" turn length = 98.99" Dia coil.

Still a 1:1 coil and there is notation of various 'tap' points on the primary and secondary to bring them into resonance.

a note also in the CSN of Tesla on Picture V. Extra coil connected to the secondary at 3/4 turns from ground connection. any idea on what 3/4 turns means? 3/4 of the turn or 75% of the total number of turns?

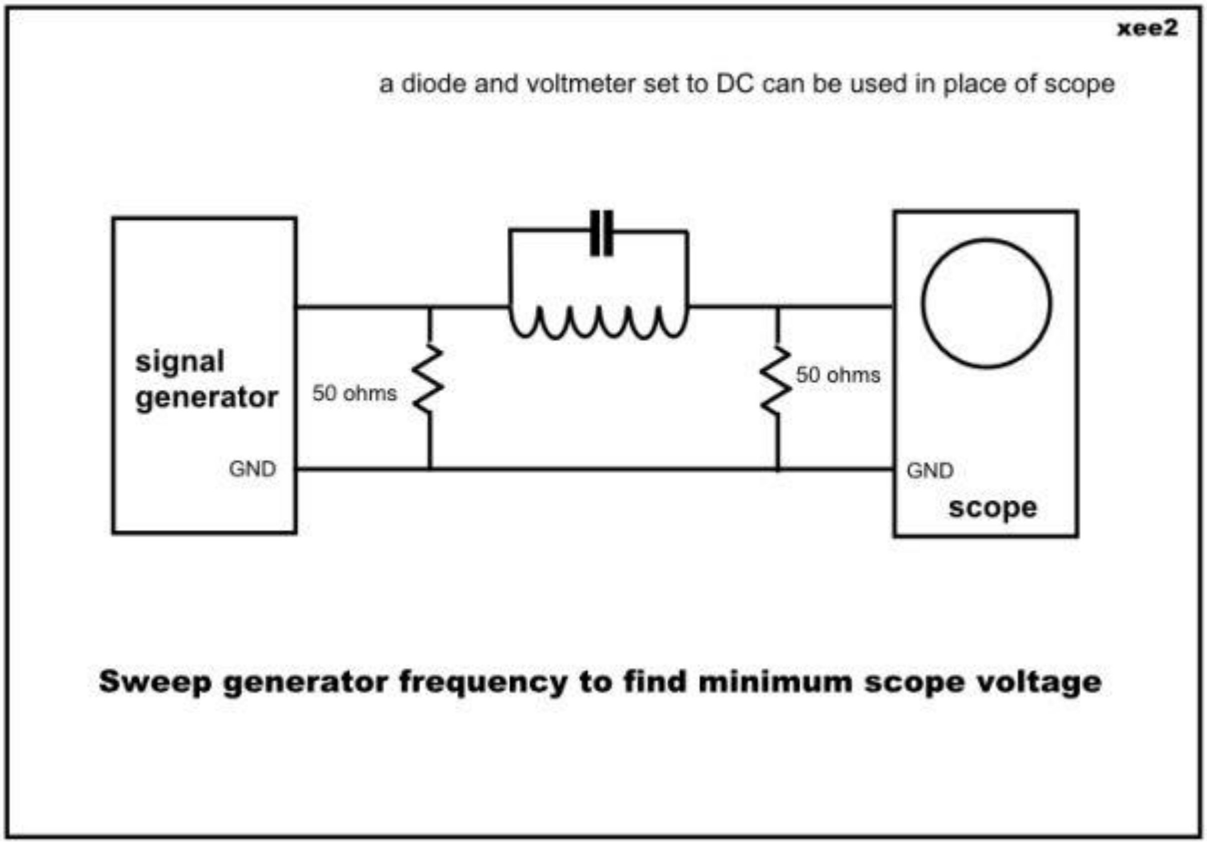
When close together the inductance of each coil will be increased by the other coil. The coil with the highest Q will primarily effect self resonant frequency. You should set SRF of secondary then gradually move primary closer re-tuning the SRF of each coil as you move them together.

This is how I measure self resonant frequency.



xee2
a diode and voltmeter set to DC can be used in place of scope
signal generator
GND
50 ohms

Extra Coil Math

Goint to be away for a week so will make an itemised listing of the Math now.

Crystal Set Iniative Extra Coil:
In brackets are the figures for my situation.

1. Write down the frequency of the local AM Radio Station you are building the Crystal Set to

receive from. (1.557 Mhz)
2. Multiply this number by pi/2 - this is the 1/4 Wave frequency (2.4457 Mhz)
3. Multiply this number by 4 (9.7829 Mhz) - this is the Full Wave frequency
4. Use your Frequency & Wavelength calculator to find the total length of wire required - this is what I use:

FREQUENCY & WAVELENGTH CALCULATOR

My length of wire = 30.645 meters or 30645mm
I use the same size awg (14) as for the Secondary which means the Copper masses are equal for all of Primary/Secondary and Extra Coils.
Length of Secondary = length of Extra.

5. Calculate Coil diameter with We = 0.4 Ws (195.2mm)
6. Calculate 1 turn using 2pi r = (613.24mm)
7. Divide this number into your total length (30645/613.24 = 49.97) = number of Turns
Suggest at this point that you wind a few extra for tuning purposes and then with Headphones on, tune for a maximum by probing back along the coil.
8. Use another tin can about 6 to 12" away from your Extra Coil to hang your 1N34 probe onto, doesn't need to be oriented in any way.
Those of you with excessive local transmitters may be blown off the map so be warned.
Mine is only a 2 Kw.

If at step 2 you were to DIVIDE that number you would arrive at the point where both Eric/Jake's Spreadsheet & Tesla would be working at.
This is in my view the wrong point as it brings you back into a 1/8th Wave and not just before the 1/4 Wave where the 0.637 'average AC Wave' becomes a significant factor.
This is the exact point where your local AM Radio Station sits at.

That's it.
Will work on the theory while I am away as I need to know the electrics behind all of this.
David,
Would be appreciated if you could get this Post to Eric as he may be able to see what is happening here.
This one he can simply copy down the instructions on paper from the phone.
First time I have ever seen a pi and average AC wave association.
Bottom line is that this arrangement works.
Goint to enjoy this holiday, first in about 5 years.
May call in while I am away.
Thanks.

Why Hard to Tune?

Have now drawn both the Multiply and Divide situations out on paper and you can see why the Eric/Tesla situation will make it difficult to tune.
In the MULTIPLY way which is my way, the 0.637 'average AC wave' point is on the UPCURVE of the frequency waveshape slope.

In the DIVIDE way that same point is on the DOWNCURVE slope.
So what we are seeing is an opportunity to tune in the first instance and only a brief and parting opportunity in the second instance.
That is sufficient evidence for me as mine required NO tuning where the other is said 'to be difficult to tune' and there is your answer as to why above.

OK have attached the drawing and hope it comes out viewable.
Math also shows the difference in length involved and how it is calculated.
Have always had this notion that all of this should not be difficult if we are to work at the correct operating points.
Thanks.

The (20%) secondary coil "effective" propogation velocity is the velocity of light in the space in which it occupies. Here the Pi over two factoris an offsetof a unit value to shorten the winding to compensate for the heavy external loading that the secondary is loaded with, that is, the external inductance and capacitance from the earth and extra coil connections. The aspect ratio of 1 to 1 on the extra coil gives an "effective" propogation of 187% the velocity of light, hence the winding length must be made greater in order to get a quarter wave resonance at a higher speed. This is brought down to Pi over 2 percent, 157%, the velocity of light to compensate for the burden upon the extra coil, this mostly arising from the dielectric upon which this coil is wound. The secondary is Pi over two shorter, the extra coil is Pi over two longer. Golly Mr. Wizard that's Pi squared over four! Do not hunt for magic where it is not, this is all experimental. So go experiment.*

This is all I know about the extra coil according to Eric.

the 0.637 is not the AC average but the rms of 1/2 of the sine wave of a DC rectified current. AC average or rms of a full wave is 0.707 or sine45*, cos45*.

If the extra coil is designed around C and harmonics at velocities of C it will only continue to receive hertzian waves. The extra coil dimensions that Eric supplied should be useless in reception of hertz transmission in air.

1/4 and 3/4 according to EPD

Quote:

> Originally Posted by **T-rex**

>
> *There is no inductance, capacitance, or wavelength. The wavlenght I gave of c/omega is not the standard wavelength. The standard way is c/f, then take 1/4th of that. That's the electromagnetic wavelength. The coils are not electromagnetic devices. Wire length is calculated by c/omega. A factor of 2pi is involved, so it's c/2*pi*f. There is no quarter. This gives a wirelength that is now 2 over pi shorter. There is no inductance and capacity to compensate or think about, the coil is both. They are not separated. Read the article in 7 parts just put in, paying special attention to the section labeled disruptive discharges. In the Colorado Springs all you want to look for is the final dimensions of the Magnifying Transmitter. Other than some circuit diagrams and final dimensions there's not much there of any use for coil design. Tesla was figuring stuff out as he was going along, he was struggling to figure out what was going on, he had nothing to work with. So read the Colorado Springs notes and share in his confusion.*

I miss the old thread and all the goodies hidden in it.

MadHatter,
You are incorrect and please read the URL I posted as it very clearly states that the 0.637 point is AVERAGE VALUE (Vav) and 0.707 is RMS VALUE (Vrms).
I have been in this game a long time and know what is what.
Please check your facts before responding to anything I have presented.
I don't mind criticism but this is BS!

Jake,
All very well but look at this:
1.557 x 2pi = 9.7829 Mhz and then go look at my drawing as it is the very same 9.7829 Mhz.
1.557 x (pi/2) x4 = 9.7829 Mhz.
All the waveshape drawing that I presented represents is the point at which we are working at with our AM Radio Station signal with respect to a Hertzian 1/4 Wave system.

If you people are not going to listen to an oldtimer with a great deal of experience in OU research, then I will just disappear into the bush just like Eric has done.

One thing I should make note of is the direction of winding.
My Primary and Secondary are both CCW but for some unknown reason I stood on the wrong side whilst winding my first WORKING Extra and wound it CW - opposite.
The new Extra is also wound CCW but does not work or is difficult to get to work and my drawing shows why.

Eric states clearly to wind ALL Coils in the same direction but I may have accidentally stumbled across another discovery which I will prove out on my return.

Not going to sit here working out all the Math problems and for all of you to not understand and discredit.
If you are so blind that you cannot see what I am presenting then I will simply fade into the distance, again like Eric.

What you may not realise is that what is being presented before your very eyes is the entire secret to winding coils like Don Smith and Kapanadze use but nobody knows why they work and all their efforts were/are of an empirical nature.

What Kapanadze is currently using is a split Copper main core and this is his Primary as he is attempting to build as Eric has shown with all the Math that I am fully supporting as shown above and replicates a Tesla Magnifying Transformer (TMT).

What the Kapanadze device now needs is the Secondary and Extra Coils to be wound using the data that I have supplied and we should have our OU device.
The only outstanding question is the direction to wind the Extra Coil and I will clear that up when I return.

I am sorry to be working with people that cannot see the light when it has all been presented before you and very clearly at that with full reference to Eric's theory and in agreement.

Didn't you hear that my Extra Coil WORKED first time using Eric's Math but on the MULTIPLY side and NOT the DIVIDE side - what do you need to see the LIGHT!?

If I am beginning to sound like Eric then you may wake up and realise why, some day.

The information passed on from this 'discovery' even shows clearly that Tesla may have made a mistake with his operating fequency and he chose the wrong side of his 96 Khz base frequency and used the 60 Khz side instead of the 149 Khz side.
This may be why he had tuning problems as his work was of an empirical nature without a solid working Math base which we now have thanks to Eric and some accidental discoveries.
Tesla may also have had technical equipment problems at the higher frequency and why he chose the lower.

WAKE UP!

Smokey

Thanks also for the info on the split copper. Zilano mentioned that also recently and about 2 years ago I came across a video that demonstrated something quite impossible looking with a split copper tube device. I was trying to get more info at the time but some said it was nothing special. Looks like maybe it is after all. I really appreciate your showing the calcs and the coil info too. I should know the calcs being a Ham but I've been out of touch so long with that it's good to see it here again as it should be easy to extrapolate any needed calcs for other frequencies or sizes from what you have shown.

In the Colorado Springs notes Tesla does mention winding half or part of the secondary the opposite way or another coil or something, I'll try to find the reference . ahah page 69 figure 2. A few of the top turns of the secondary

Cheers

Smokey,

Math does not mean much to me. Sure it's a tool that simplifies life but to me.. It's just numbers, there all relative.. I need to understand... Once I do that the math is a piece of cake...

I see the Dollard quote as being directly related you your situtation. You did it... Now don't give up on us. Because we are trying to catch up.. It takes us more then two days to build something new. We are trying. I don't have 20 years coil winding experience. And we are in the middle putting together the "whats going on" or at least I am

Now buck up, get back to work, and tell us what happens with your next extra coil.... I'm taking notes, trust me...

@ David G Dawson

It is great to have someone who understands what EPD was doing. Can you explain the purpose of the "primary" copper sheet coil. As far as I can tell it is just adding capacitance to the secondary coil by way of mutual coupling.

Yes, it is the average value, my mistake in calling it rms. It is the average of half the sine wave and is normally applied to a rectified waveform.

Look forward to your results, and further development of the equations your using.

a diode and voltmeter set to DC can be used in place of scope
signal generator
GND
50 ohms
50 ohms
GND
scope
Sweep generator frequency to find minimum scope voltage
resonant frequency test

6 - 330pF across the primary and the system is happiest at 1640. It is now louder with only a ground(house ground) than it was with the fireplace antenna and I can listen to the piezo earpiece well without even touching the diode to the secondary. It will also light an led.

So now I need that 2 plate capacitor I was talking about earlier. That way the capacitor metal will match the primary metal.

David, you're not going to like this and I mean no insult to you at all. Your calcs are still based on the velocity of C, Eric is clear and adamant that this is wrong! any and all variations of the harmonics based on the propagation speed of light will result in the wrong direction being taken.

If I have somehow missed where you've taken this into account please point it out to me

I agree with Eric on the increased velocity propagation to what extent is where it needs fine tuning. the rotation of the B field is where the velocity start to increase and is a cos value, how far that rotation is, well... that's a good question.

The (20%) secondary coil "effective" propogation velocity is the velocity of light in the space in which it occupies. Here the Pi over two factoris an offsetof a unit value to shorten the winding to compensate for the heavy external loading that the secondary is loaded with, that is, the external inductance and capacitance from the earth and extra coil connections. The aspect ratio of 1 to 1 on the extra coil gives an "effective" propogation of 187% the velocity of light, hence the winding length must be made greater in order to get a quarter wave resonance at a higher speed. This is brought down to Pi over 2 percent, 157%, the velocity of light to compensate for the burden upon the extra coil, this mostly arising from the dielectric upon which this coil is wound.* ***The secondary is Pi over two shorter, the extra coil is Pi over two longer.*** *Golly Mr. Wizard that's Pi squared over four! Do not hunt for magic where it is not, this is all experimental. So go experiment.*
>
> .

If the secondary is Pi over two shorter, the extra coil is Pi over two longer what is the actual length in rad.

It been a long time since I worked in radians. Is this correct:

pi/2 shorter = ((3*pi)/2)*'?'
pi/2 longer = ((5*pi)/2)*'?'

?= cycle or wave or...

Pi/2 = 1.5707
1.57... rads is 90*

Pi = 180*
1 rad = 180*/pi = 57.29577*

90* is the multiplication of -j rotation. reference to Steinmetz and the operator, also it's the rotation of the B field and hence the reason for the increased velocity.

The secondary length is given by C/omega or C/(2piF). As stated by Eric this is pi/2 shorter.. Shorter than what(w)? [pi/2 = 90* = 1/4 cycle]

So pi/2 less than one cycle is 3pi/2 or 3/4 of a cycle.

So what is the standard that we are taking away from? In terms of pi.

The secondary is in radians not degrees, so the wave length is equal to it's arc length.

Erics comment of the pi over two longer or shorter is by my understanding the reference to -j operator which is a pi/2 multiplication rotation of the B field.

I'm working on some other relations for the extra coil at the moment using hyperbolic trig and will post as soon as I have something.

I wanted to post a comment.
I realize that we can twist and fiddle fart all we want with the mathematics to get results we want. the math in reality should be the theory and the experimental lab work is testing that theory, when it doesn't match or the results are different its back to the drawing board to re-do or re-calculate the math again.

Math is a VERY powerful tool in setting up a theory and testing it. If there is a pattern where experimental results fit the mathematics used then expanding on the mathematical theory gets a bit easier however one still has to be careful that we don't start to effect the results by manipulating the results thru the mathematics used.

Thankfully a lot of the base math is known and results are predictable, we are though when getting to the extra coil moving into the unknown. coil winding and manipulation of fields thru various winding designs is nothing new, this is not what Eric or Tesla was doing though. instead of trying to force or manipulate the fields Tesla was using the base parameters of the fields to manipulate them. Steinmetz covers this with the J operator in hyperbolic form, Clifford algebra is another useful tool though it's basis was quaternions - another story for another day!

The goal is to get to L&C to match in harmony, nondestructive resonance. once achieved there should be a rotation of the B field to where the conjugate pair is no more, this will give rise to velocity of the wave faster than C. simple in theory but highly complicated in practice due to the sheer number of parameters involved and that the mathematics for engineering this are not finished.

Now here's the 64 trillion dollar question (inflation), when the B field is longitudinal to the E field, is the extra coil still inductively coupled to the secondary? or is it now in electrostatic phase coupling? it needs both to achieve resonance, but once there what happens? is it the elusive sink and radiator Steinmetz theorized?

Jake's crystal radio

you don't need a full bridge rectifier or capacitor for the LED, or at least I don't. single diode and led with leads shunting top and ground will light the LED nicely.

@ madhatter

Thanks for the info. How far are you away from the transmitter? I would try this but the nearest transmitter to me is about 50 miles away.

I know nothing about this antenna design, but as an ex-ham the top coil looks like an inductive matching coil that is used on ham whip antennas that are shorter than 1/4 wavelength. When the whip is less than 1/4 wavelength it looks like a large capacitive reactance. Putting an inductor in series with the capacitance cancels out the reactive components and makes the whip look like a small real impedance instead of a large reactive impedance. This makes it easier to get power into and out of the whip.

Ahh, well the radio setup was too problomatic and that transmitter is roughly 36miles away.

I turned my attention to smaller scale and built two sets CW and CCW coil sets at 4Mhz.

This is a bit different from std radio reception, the secondary is in radian length. but the extra is very different. It's basic design is based on the propagation velocity increased by 157.08% over C. which increases the length to fit the increased wave length.

the secondary is 1.570 radians in length or 90*, the extra is also the same 90* but at the increased velocity of C by 157%. the spacing and wire ga are designed to create a self resonance within a 1:1 H/D ratio. As you can imagine nearbody capacitance becomes an issue as it's highly sensitive. The extra coil calcs seem to confuse many as well, there is a fair amount of information by Eric Dollard on the reasons and research behind the equations.

It starts from the point that the speed of light is due to the conjugate pair of E & B fields, now by rotating the B field by theta degrees it is possible to increase the velocity by cos(theta).

Jake's crystal radio

I started with something very similar to that schematic. But then the ground line from the FWBR came off and it still worked fine with little to no difference. It actually worked better if I held the ground line instead of attaching it to the bottom of the secondary. That reminded me of an AV plug so I tried one and it worked, so I stopped using the FWBR.

The secondary has nothing attached to it except the soda can terminal and the ground. The soda can terminal is optional and the size can be changed to for more or less capacitance. I don't know exactly Eric recommends the can.

The primary has almost 2nF of capacitance attached to it. (6 silver mica in parallel) This will be replaced with a 2 plate capacitor. The LED and Piezo earpiece are both attached to the same AV plug. The piezo is in parallel with the LED on the AV plug. This can be touched to almost any part of the secondary or primary for a listen. It will start to pick up audio about 1" away from the coil.

If there is not enough capacitance on the secondary (not across), hand and body capacitance plague the system. You need to be near it to for it to work. Once I had enough capacitance I could approach without much issue but if I get with 1" it shuts down.

I went with the soda can on the secondary which gave me an SRF of ~2000kHz for the secondary alone. Adding the primary brought that down. Adding capacitance to the primary keeps bringing it lower. But there is a cost in efficiency.

Adding capacitors across the secondary was difficult because I needed so little capacitance. One lead from the top and one from the bottom laid close together was about as good as I could get. Or I could just hold my hand about 1 inch from the coil.

What did you use to draw the schematic?? I need something like that.

The question remains is this all related to TEM?

I'll get better at the schematics.

Thats what it looks like today. Replacing the can with 1 turn 1/2" copper tube made very little change. All of which could be offset by tube hight or capacitance on the primary.

I finally finished the extra coil for the other set. So now I have two sets, one CW and one CCW.

Setting them up in series so that the two primaries are back to back and axial the entire series will resonate at 4Mhz, that took some fiddling.

disconnecting the extra coils and leaving them inductively coupled, and the two primaries inductive as well. setting about to tune the extras has been strange, the CW extra tuned easily enough, the CCW extra, nope. I've removed 3 turns got it as far as 3.5Mhz adding capacitance lowers it and I don't feel comfortable removing more turns. something odd with this setup.

For an experiment I fed the two primaries the same signal from the generator, so that signal goes to outer turn of CW and inner turn of CCW, opposite for ground lead. the secondaries are in series with a small capacitor and the free end has 7sq/in of aluminum foil as capacitance on it.

the extras are sitting horizontal so that the axis is vertical, they are sitting 45* off plane of the primary secondary axis at roughly 1.5" from the secondaries edge. top of each extra has 2sq/in of foil. the top of the CW extra is an LED with two diodes. The led lights brightly at 4.1Mhz, placing my hand anywhere near the secondary kills the light, near the extra has no effect. taking the LED circuit and placing it on a wooden dowel and moving about the entire arrangement the

LED lights only when touched to the extra or secondary foil end. If I take the circuit and hold it via a plastic clip and move it about it will light when near the secondary free end or extra coils, my body capacitance seems to enable it to light wireless.

I'm only feeding it a 0dbm signal at .5vdc. CW extra coil measures ~3vdc wirelessly.

strange indeed. Oh and the magnetic field near the extra coils is lower then background field! very very weird.

@ jake

The following test would provide a good measure of how well your crystal radio is performing. Find highest output voltage you can get with a specified antenna length.

It will show 2-3v avg. or 5-6v peak to peak if I set it up like that. No antenna. The digital multimeter and DSO nano average values are close.

BUT it needs to be grounded to something in my house or attached to my house, or "virtual grounded" to a copper plate on the counter. The entire electrical system including the mains ground and water pipes all are contaminated with the signal. i.e. I can faintly hear the station with just a diode and no coils..

Outside with a wire stuck into the ground away from the house I just get a signal of ~50mv. Without the wire in the ground I get nada.. (I need to work on a good ground)

Primary capacitor plate and lead

Its going to be dificult to solder this to the primary. I have two of these. The other is the mirror image.

Soldering is best, but just fastening with screws should work.

Is this 50 mV with the resonator?

I think the secondary should be mostly left alone. It can be tuned for best signal by using adjustable condenser plates across it, and the primary also tuned using variable capacitors. One affects the other. This can all be seen on an oscilloscope across the primary. The plate connecting to the diodes "sucks" energy out of it and the voltage in the primary is lowered, also the plate itself affects the tuning so the condenser plates need to be adjusted to compensate. Using a simplified "power" setup with no load makes all this easily visible.

I also get a higher voltage in the primary at 1.4-2.something MHz when the station I'm tuning to is 882kHz, there's only noise at the higher frequencies/higher voltage, so I don't think just measuring the voltage is an accurate way of tuning it or any reliable way of determining what's

going on. The signal should be in the primary otherwise there'll be no possibility of powering anything. The radio setup isn't arranged across the primary as a regular Tesla type receiver, rather in this case the primary is just having a resonant effect to maximise the "radiated" signal at the top of the secondary for reception through the plate antenna. In my opinion 🙂So I'd say the place to be looking is mostly at the primary.

Yes, just like the last sechmatic you posted. With ~2nF on the primary and no antenna.

What simplification? Please elaborate.

Quote:

With only the primary setup, (coil and capacitor) and the secondary (no capacitor), No terminal.. and grounded to the house mains or metal fireplace. There are two points of interest. One when the point of highest "activity" is at the top of the secondary, the other is a bit off that when "activity" is highest at one terminal of the primary condenser (only one the other terminal shows nothing).
At both of these points it will wirelessly light an av plug(led and 2 diodes in circle) about 0.25" away.

I'm not sure what makes an av plug light an led wirelessly. I thought it was high voltage but there is none of that here.
It is a loop and it is in the near field so it might be induction??

Anyone know what making the led light up?

This is the normal high voltage point at resonance.

I suspect your radio is working with the house ground because there is a good ground at the circuit breaker box for the power lines. I also suspect that the circuit is not working outside because you do not have it well grounded. Your soil probably has too little moisture to provide a good ground. Grounding to dry soil is like not having a ground. For the ground to function it must have good conductivity to a large area. Even if there is not a good ground for the power lines, the wiring in your house covers a large area with good conductivity which is probably large enough to be a good ground.

However, I am puzzled by your being able to get a signal without the coil. This may indicate that the power line ground is not very good and the house wiring is acting like an antenna.

If you remove all the diodes from the radio setup and the load from the power setup then you are left with only a capacitor across the primary so a very simple arrangement. As far as I can make out the bulb affects the capacitance/tuning so the 2nd cap is possibly in series with the bulb to reduce the extra capacitance. Either way if you just use the single cap and no load you can see on the scope how the reception (or "activity" in the primary) changes by adjusting the primary capacitance and the secondary condenser plates accordingly.

With my spiral for example by setting it up like that and tuning for best signal in the primary with no loads at all except a scope, to hear the radio all I need to do is place the C0 plate from Eric's radio diagram 25+cm away from the secondary terminal. That reduces the voltage in the primary but not too much because it's so far away relatively. This is probably where the flat spiral and TMT start to differ more significantly, but employing variable condenser plates and a separate receiver/C0 plate is a big improvement over using the C0 plate as both the receiver and tuning condenser, before needing to be within 5cm distance of the terminal to bring the frequency down enough and still hear the radio. Now it's already tuned without the C0 plate as can be seen in the primary.

Does the LED still light if you remove the speaker? It could be acting like a microphone although I don't see why it would work only in certain places in that case. It would be interesting if it still lights without the speaker

The ground component is the next item on my agenda as soon as the large plate primary condenser is working at the same level as the current set up.
Thanks to recent Dollard transmissions on his thread I can finish that up. without excuse.

But the ground is still a mystery to me. Important as it is, how it is supposed to fuction is not clear in my head. I want to lay the ground system, one piece(radial) at at time and get a feel for what changes it makes to this setup. I also have not decided if I want to use the 17 rod or 80 wire radial Eric recommended.

Nice, you just made me notice that the radio setup doide/capacitor/high z arrangement looks like the "AV plug / speaker" I made. Just replace the capacitor with the LED.

>
> *Does the LED still light if you remove the speaker? It could be acting like a microphone although I don't see why it would work only in certain places in that case. It would be interesting if it still lights without the speaker*

Yes it will light without the speaker. I have three different plugs I have been playing with. They all light the led.
One is just like the one in the picture. Another is just like that but also has a ~50pf cap across it. The last does not have the speaker or capacitor.

Capacitance is needed on either side of the LED between the diodes and LED. I can hold it or sometimes just attaching an lead will work. If I feed it a signal using an extra 1 turn tuning coil it will light without the capacitance on the LED.

ALSO and a bit off topic but... IF YOU THUMP THE CRYSTAl SPEAKER THE LED BLINKS SUPER BRIGHT... It cought me off guard. And took me about 10 seconds to realize what happened.

I knew the potential for that to happen was there but I never thought it would do that to an LED with a little tiny thump.

now back to work.

There's more material on the Eric Dollard thread, the recent writing on the Bolinas Antenna that applies to this. There's more information on the subject there. Eric asked me to make sure you guys saw that information. Also a lot of your questions have been answered there. Eric also said he is very impressed with your guys' work so far.

Thanks, I always try keep up to date on the Dollard thread. Great info. I hope Eric knows how much we appreciate his experience, direction and help.

@ all,

When I took my primary off to try and solder on the capacitor I realized that I don't know which way it should be wound.

Do you wrap in the same direction as the secondary, then overlap the first turn? (that's how I have it now) OR after one turn go under the first turn?

Does it matter?

Also how close are the turns on the primary? Eric said closely spaced. Does that mean as close as possible. I have about 1/8" spacing now but I was thinking I could get closer and use paper as the spacer. It becomes important to know this before you add you capacitor. Changing the spacing after I have attached the capacitor will cause the plates to be misaligned.

What effect does spacing have on the primary and how does that carry over to the secondary? I tried to experiment with this but I noticed that if I make the spacing larger I end up shorter on the number of turns. That is changing two variables at once and I can't draw any conclusions.

My thoughts are with 2 turns fixed: more spacing = more inductance(increased area), but also less capacitance between turns. ???

Thanks,

I would say that it does not matter for capacitance. However, the current flow should be in the same direction as the secondary turns. The spacing between turns changes the self capacitance of the loop. Less spacing equals more capacitance. Moving turns closer together is like adding parallel capacitance so it will effect the tuning.

Post numbers here refer to the Crystal Radio Magic Thread

Post 73, Jake.

Standing wave on coil indicates proper operation. A voltage node must exist exactly at the neutral terminal. Tesla could move this node about in the earth. This is important and in an optimum state the voltage node is right at the point of earthing. A projected wave velocity exist on the earth surface, infinite at the earth connection, and luminal 90 degrees around the planet. It is a tangent function with Pi over two as the "Effective velocity". Hence velocity here is only a projection on the earth surface, not a true velocity, like your shadow at sundown it goes to infinity.

Post 136, Madhatter.

The B field is a bad way to look at this. It is a physics dingleberry. B is a dimensional relation with a per centimetre square. Here it is best to use versor magnetic induction k Phi, see last part of Theory of Wireless Power. Mutual inductance is longitudinal so that coupling remains for concatenated longitudinal resonators. Wave direction now has a role in coupling.

Post 143, Madhatter

Wave direction coupling makes balance to unbalance transformation impossible, this gives the "dead phase" extra coil. If it is a balanced system, every part of that system must be push-pull. Unbalanced unit has neutral on one side of primary, a balanced unit has neutral on primary center tap. All concatenated coils must be wound in same direction as wave propogation spiraling around them.

Post 156, Jake

Do not replace 100 pF condenser with LED, it will distort and rob power from the audio. Use a completely separate setup for LED. Try Ne 2 neon lamps. Also a 10-15 watt fluorescent lamp is a good standing wave "wand", this for tuning.

I would recommend using a GSN7 Triode section with cathode drive from function generator and the primary as the plate tank circuit. See the figure. This will greatly improve resonance for tuning. 50 Ohm across primary NFG, GSN7>6000 Ohm general.

Multiple tuning peaks indicate overly tight coupling between coils. Slowly separate them until only one resonant peak. Multiple modes of stray reception and strong local stations will make grounding and tuning very confusing. An isolation amplifier GSN7 triode isolates amplifier from function generator interaction and gives more power to light neon lamps. Both sections of GSN7 in parallel give more power.

I'll re-review that, also I was pointed towards the 2002 Oerstad Medal Lecture that covers the need to use geometric algebra -Clifford algebra- to reduce the fragmentation physics has undergone with the avoidance of vectors.

I figured that may be the issue when driving the CW set and then placing a sheet of plexi between them then the CCW was able to be tuned. more experimentation to follow as time permits.

Thanks for the input and the time to respond to our efforts here.

Have you read any of Julius Adam Strattons' notes? I was going over his notes on electromagnetic theory from 1941 as he has what I've found to be the most coverage of electrostatic energy and fields.
excerpt:
Conductors play an especially prominent role in electrostatics. For the purposes of a purely macroscopic theory it is sufficient to consider a conductor as a closed domain within which charge moves freely. If the conductor is a metal or electrolyte, the flow of charge is directly proportional to the intensity E of the electric field: J = aE. Charge is free to move on the surface of a conductor but can leave it only under the influence of very intense external fields or at high temperatures (thermal emission). If the conductor is in electrostatic equilibrium all flow of charge has ceased, whence it is evident that at every interior point of a conductor in an electrostatic field the resultant field intensity E is zero, and at every point on its surface the tangential component of E is zero. Furthermore the electrostatic potential within a conductor is constant and the surface of every conductor is an equipotential. Let us suppose that an

uncharged conductor is introduced into a fixed external field E . In the .first instant there occurs a transient current.

POSTS FROM THE Eric's "Crystal Radio Initiative" Challenge THREAD STARTED BY SEBACID

⚠Eric's "Crystal Radio Initiative" Challenge

I thought this challenge needs some promoting to get us all involved in it.

I want people who are taking on this challenge to post their progress, results, questions, photos etc. in this thread.

Basically anything that involves this challenge belongs to this thread. We can assist each other in problems, setbacks, windings etc. and generally work together in completing Eric's challenge.

The objective would be to see how many of us can successfully complete this challenge. Hopefully it also encourages more people to experiment in this field.

Remember, the idea of the challenge is to get us *thinking* and *doing* things on our own, so please try it yourself first, then if you hit a wall that you can't breach, post here and ask help.

Don't give blueprints or schematics for a working system! If you manage to complete this challenge, post the date of completion here and we can compare results later in another thread specifically made for complete, tested and working setups.

In short, get off your monitor and start experimenting! 😉

Hi Sebastian,

What specifically is this challenge and where can I read up on it?

Best regards,

Luther

Hi Luther,

The challenge is located amidst the jungle in this forum in Eric's posts as T-Rex.

Here is a short copy describing it:

"The objective here is to scale the “Crystal Set”, a step at a time, into a Tesla Transformer for the reception of medium wave band, 300 – 3000 kilocycle A.M. broadcasts. No license is required for this and the broadcast station provides the power.And this objective cooperates with the primary objective. That is; Who will be the first ham to disprove Einstein’s theory? An International contest, but who will sponsor it, Iran maybe?We have the good fortune in the “Crystal Set Initiative” that, in theory at least, a quarter wave A.M. broadcast tower, and its 120 quarter wave ground radials, must emit a pair of waves as shown by Tesla in his basic diagrams.

Hence it can be seen that a pair of waves are engendered by this transmission system. (Tower and Star Radials). One wave, Hertzian, is the over ground wave, the other wave, Telluric, is the under ground wave. These two waves arrive at the point of reception in their own distinct time frames, giving rise to a difference in phase. Hence, multiple rings of interference patterns are produced. Since the Hertzian portion, over ground, time frame is based upon the velocity of light, then the Telluric portion, under ground, time frame gives the Telluric velocity. Two crystal sets, one over ground, one under ground, and a basic oscilloscope , that simple. I have done this at Landers.Concluding, a Tesla Magnification Transformer, properly proportioned can, in theory, actually draw power from a local 50 kW station. Several hundred watts of power reception is likely. This would prove Tesla once and for all. No antenna, just a good ground, and a nice and bright 100 watt light bulb.This would overturn physics more than any billion dollar C.E.R.N. project. A ham radio operator overturns Einstein for 100 bucks. What a concept."

Read,
Tesla, “The True Wireless”
Tesla, “System of Concatenated Tuned Circuits”
Dollard, “System for the Transmission and Reception of Telluric Electric Waves”
A.R.R.L. “Radio Amatuers Handbook”. Chapter “H.F. Transmitters, & Tank Circuits”

Here is another link that has most of Eric's posts shortlisted:

What would this look like?

I have looked at this and done a bit of reading at the context and I don't really have a good feeling for where to start. I am thinking perhaps I should apply some of the functions and formulae that EPD has gathered and perhaps compute the size and other parameters of the necessary coils and capacitors? If someone would suggest some specific numbers and create an example of the calculations, that would seem like a helpful starting point. First, pick a typical AM frequency, such as that of your local 50 KVA AM station, and use that as an example. It seems we need to solve a simultaneous equation. There are two values for inductors and also two? values for capacitors. Then there is the actual circuit diagram. Again, I have a picture in my mind, but I'm not sure if it is right. If you want to post you sample data, my eyes are open. Thx.

Hi Wayne,

All the information necessary to do this can be found in this forum under Eric's posts as T-Rex. See links in my previous reply. You just have to get your hands dirty and look for the information. That is a part of the challenge, to get people *doing*.

But here's some advice to get you started:

"The design of the Tesla Transformer starts with the secondary resonant coil. In its resonant mode it is a quadrapolar resonator. Two constants exist in the construction of this solenoidal resonator, one is that the height to length ratio must be 20%, the other is that the side by side spacing of the cylindrical conductor turns is 62% the diameter of the cylindrical conductor. The optimum number of turns is 20 on the secondary, with 2 on the primary. This gives the physical size of the coil for a given frequency. Increasing the number of turns reduces the size of the secondary coil in proportion to the increase in turns. Accordingly the conductor diameter also decreases as the copper is spread out over more windings. The ratio of secondary turns to primary turns must equal a constraint of 10 to 1. For a given number of turns the operating frequency becomes the sole independent variable in coil design.The primary coil is the same diameter as the secondary coil. The ratio of conductor width to coil diameter is 18%.

The sheet conductor is closely spiralled into two turns, for a secondary of twenty turns. For a conductor thickness as given by the maximum thickness vs frequency the volume of the primary metal must equal the volume of the secondary metal, based upon equal weights for primary and secondary metals. Brass can be 1.7 times thicker than copper, and bronze can be 2.8 times thicker than copper, for a given maximum thickness and frequency.The primary condenser should be made of the same amount of metal as the primary coil. Their weights should be about the same. The connecting leads must be short and the same width as the primary conductor.

Large, multiplate air condensers are good, so are metal sheets and glass.The secondary capacitance is best a copper tubing ring around the outside of the H end of the coil. This ring must be open in one spot along its loop so as not to be a shorted turn. The end of the secondary wire connects to this capacity ring. Beer cans make the best elevated capacitors.The finished transformer must operate on a directly connected ground plane. A large plywood table with aluminum foil glued on to it, this covered with a plastic or glass sheet is the minimum required ground plane. Obviously the aluminum plane must be solidly earthed with special attention to minimizing ground lead inductance. In order to light a lamp a more broadcast station style of ground plane is required, but for testing purposes the metallized plywood “ten by” sheet is just fine. Good luck and good crystal set DX ing.

Sample calculations

OK, based on your suggestions and the calculations you have posted, I can visualize the transformer. It will be small enough to hold in one hand.

Here is what I have done so far:

I will be using 750 KHz as my center frequency as an example. This frequency is used by the famous WSB.

WSB is a 50,000 watt clear channel broadcasting station in Atlanta, GA.

The antenna is located in Tucker, GA according to Wikipedia.

Calculation #1

L = Total length of coiled wire

L = f/w = 299,792,458 (meter / second) / 2 * PI * 750,000 (/second)

= 299,792,458 / 2 * 3.14159 * 750,000 (meters) = 63.62 meters = 63.62 meters * .3048 ft / meter

= 19.39 feet

Calculation #2

L = Length of each turn = 19.39 feet / 20 = 0.9695 feet = 11.63 inches

Calculation #3

Circumference C = L; Diameter = Circumference / PI = 3.7 inches

H = Coil height = 0.2 * Diameter = 0.2 * (11.63 inches / PI)

= 0.74 inches

Calculation #4

Max diameter of wire. Space between strands of wire is 62 percent of wire diameter.

20 turns take 0.74 inches ===> 1 turn takes 0.74 inches / 20 = 0.037 inches

0.037 inches = 162 percent of wire diameter ===> 100 percent of wire diameter = 0.037 / 1.62

Wire diameter = 0.02286 inches (max.)

AWG 23 has a diameter of 0.0226 inches / 0.573 mm.

AWG 23 has resistance of 66.79 ohms / Km. which is 20.36 mOhms / ft.

For 19.39 ft, the coil will have 395 mOhms or 0.395 Ohms resistance.

I thought it would be larger than this. So much for my intuition.

> *I thought it would be larger than this. So much for my intuition.*

There is a small mistake in your calculations...

L = Total length of coiled wire

L = *f/w* THIS IS WRONG, it should be c/w! (but you have calculated it correctly) = 299,792,458 (meter / second) / 2 * PI * 750,000 (/second)

= 299,792,458 / 2 * 3.14159 * 750,000 (meters) = 63.62 meters ***= 63.62 meters * .3048 ft / meter***

= *19.39 feet* THIS IS WRONG!

If converted then 63,62 meters gives roughly about 209 feet (63,62x3,28=208,67).

That shouldn't fit in your hand anymore... ☺

Remember you need two different setups, one wave, Hertzian, is the over ground wave, the other wave, Telluric, is the under ground wave. These two waves arrive at the point of reception in their own distinct time frames, giving rise to a difference in phase. Hence, multiple rings of interference patterns are produced. Since the Hertzian portion, over ground, time frame is based upon the velocity of light, then the Telluric portion, under ground, time frame gives the Telluric velocity. Two crystal sets, one over ground, one under ground, and a basic oscilloscope , that simple.

A great link for most information needed is provided in my first answer in this thread. Happy experimenting!

Just finished my calculations for my secondary coil and it will be a whopping 76cm in diameter! I am going with 1000Kc/sec Frequency.

I finished the work on the wooden bases and supports, all that is left is to bake and laquer them before assembling.

My extra coil's diameter/height is going to be 30cm.

Some calculations with other stuff is still going on, but I'm going to build two identical coils of the exact same size, one for overground Hertzian wave reception and the other for underground Tellurical wave reception.

The coils will be identical but the setup will be different as the goal is to light a 100W lightbulb with the other coil.

We'll see how things go once I have built them.

Thinking of replacing solid wooden supports, with hollow pvc tubing (thin) to minimize stray inductance? Any thoughts on this?

Hi Sebastian. Yes PVC tubing will be better than wood. Also ideally you should design the coil for a specific frequency/radio station, 1000 kc is a general example. When tuned to different frequencies the magnification factor will alter, the goal is to have highest magnification factor at the intended frequency so different tuning will work against this. Although you will need to experiment to find the highest magnification factor with a given design anyway.

For the overground wave reception you should use a normal crystal radio or a normal radio receiver. You need to receive the signal as normal and then measure the difference.

Hi Dr. Green,

Thank you for your insight, I will have to do some searching on a AM radio station near me (Finland). The problem here is that almost all of the broadcasting stations have ceased using the AM frequencys. I think the nearest one is in Holland?! Not sure on this, must check.

In the calculations for the extra coil, I get a totally different total lenght of coil if I use the formulae by Eric to calculate it?

Tesla's Colorado extra coil had the same amount of wire as the secondary (800m). Should I go with this or trust the formulae?

Thanks again,

-Seb

Post edit:

Found a radio station from Sweden, Stockholm radio that broadcasts at 1710Khz AM frequency. I think it is still operational, so I will try working with this frequency. The last AM radiostation in Finland ceased to operate in 2007. Any other known operational frequencys are welcome! 🙂 Time to do the calculations again! 🙂

I forgot to mention, use white or clear etc plastic rods. Apparently to make black and grey they put carbon in it, so that won't be good.

Eric's design is different to Tesla's. Eric's theory involves concatenated resonance with the extra coil as a distributed network, whereas Tesla's is lumped. So it's completely experimental. I've tried 3 different extra coil variations, and Eric's latest comments on it was that the secondary might need to be of a lower inductance, so my latest design is a bit different. I have 17 turns secondary with 15% height to diameter ratio, and the extra coil, when calculating wavelength from frequency and speed of light, has 1.19 times longer wire length because of the "faster than light" propagation, wire length is extended to bring the frequency back down.

[edit] Probably the easiest way to find whether a radio station is operational and suitable or not is to use a radio. When you find one then you can find info on it on the internet.

for accurate time comparison how do you compensate and adjust for delay differences that result from the inherent design differences between the telluric and atmospheric versions?

and one more....

how do we calculate the maximum theoretical (ideal conditions) power that can be drawn from a transmitter with a particular receiver design/situation

Use an oscillator and tune both receivers to be in phase.

This is out of my league

Correcting my error and still using 750 KHz as my center frequency, this is what I get...

Calculation #1

L = Total length of coiled wire

L = c/w = 299,792,458 (meter / second) / 2 * PI * 750,000 (/second)

= 299,792,458 / 2 * 3.14159 * 750,000 (meters) = 63.62 meters = 63.62 meters / .3048 (meter / ft)

= 208.7 feet

Calculation #2

L = Length of each turn = 208.7 feet / 20 = 10.44 feet = 10 feet 5.23 inches

Calculation #3

Circumference C = L; Diameter = Circumference / PI = 3.32 feet = 3 feet 3.86 inches

H = Coil height = 0.2 * Diameter = 0.2 * (10.44 feet / PI)

= 7.97 inches

Calculation #4

Max diameter of wire. Space between strands of wire is 62 percent of wire diameter.

20 turns take 7.97 inches ===> 1 turn takes 7.97 inches / 20 = 0.4 inches

0.4 inches = 162 percent of wire diameter ===> 100 percent of wire diameter = 0.4 / 1.62

Wire diameter = 0.246 inches (max.)

AWG 3 has a diameter of 0.2294 inches / 5.83 mm.

AWG 3 has resistance of 0.646 ohms / Km. which is 0.197 mOhms / ft.

For 208.7 ft, the coil will have 395 mOhms or 0.4111 Ohms resistance.

Now we have a manly sized inductor! 'Sorry to say I will not be building that any time soon! Thanks for the ride!

At the same time, my intuition was telling me this was going to be a large coil. So, I feel a bit better knowing my gut was in the ballpark.

You can always use another frequency (higher), then the coil, wire etc. size will be smaller. Try for something in between 2000-3000Kc/sec? As Dr. Green said earlier, the idea is to magnify the chosen frequency to the max!

Don't give up, build a smaller one first, experiment on it and if succesfull, upscale it on the next one!

Cheers,

-Seb

Wire?

Does it matter if I use insulated wire for the winding? Or is it better if it was copper?

Every insulation will increase the self capacitance. Now I think it was better to keep that one low as possible.

Apart from that be careful with the material you use. If there is Orgon than organic materials like wood or materials like coper are preferable. In another type of research we found out that Orgon does become sickening if you use the wrong materials that your body does not like when you would eat or drink them. I would be careful with pvc that contains chlore. Even the thin insulation on the coper wire might be wrong. But this is only important if you want to make a coil that does not make people get an head-age.

I was experimenting with crystal sets last year
Was listening to clear channel stations 2 states away at night with crappy antenna. Powered piezo headset i made. no power source for radio except radio waves. I learned a lot doing this. was gonna try ground antenna next Harris Rogers style.

I hope this isn't a completely question - When he says "Total number of turns", Given 20 - what does he mean by 20? Would that be 20 turns per inch?

The same for the next formula, "Given 20%" What exactly does that mean as well?

Please pardon my ignorance. I've got all the components together to start on a crystal radio - I want to fully understand before proceeding though.

Thanks,

"Total number of turns = 20" means exactly what it says. 20 turns in total on the coil.

The 20% is in reference to the height/length to diameter ratio of the coil. The coil is 20% high as it is wide. If diameter = 100cm then height = 20cm.

Crystal Radio Kit 4
Mike's Electronic Parts, LLC

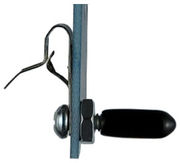
Crystal Radio Kit 4 is a great way to get started in electronics and radio building. This is a fun and simple project for both beginners and expert builders alike. Everything needed to build a fully functional radio, including an antenna and ground wire, is included in the kit. Easy to assemble with no soldering required. Crystal Radio Kit 4 is a great project to build with your child or grandchild, boy scout groups and schools.

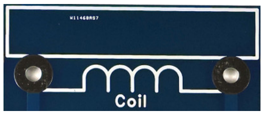
The kit contains small parts that may be a choking hazard. Adult supervision is always advised while building the radio kit.

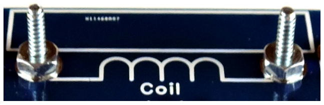
Assembly

1. Locate and familiarize yourself with all the parts in the parts list.
2. Assemble the legs.
   Items used: 4 - 3/4" #6 Screws, 4 #6 Nuts, 4 - Fahnestock Clips, 4 - Rubber Feet.
   Insert a 3/4" #6 screw through a Fahnestock Clip. Insert the screw with fahnestock clip through the circuit board. Attach a #6 nut from the bottom side of the circuit board. Snug the nut, do not over tighten. Push a rubber foot over the bottom of the screw. Lightly turn the rubber foot clockwise to ensure it is fully pushed into the screw.
   Repeat for all four legs.

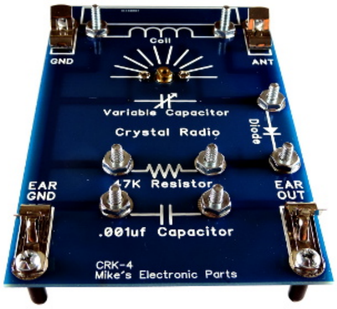


3. Assemble the coil screws.
   Items used: 2 - 1/2" #6 Screws, 2 #6 Nuts.
   Locate the Coil location on the circuit board. Insert a 1/2" screw through the circuit board from the bottom in the hole to the left of the coil schematic symbol. Use a #6 nut from the top to fasten the screw to the circuit board.
   Repeat for the hole to the right side of the coil schematic symbol.



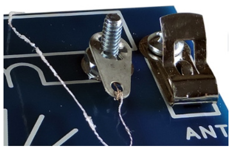


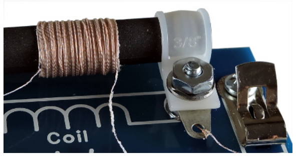
4. Assemble the posts.
   Items used: 6 - 3/8" #6 Screws, 6 #6 Nuts.
   Push a 3/8" #6 screw through the circuit board from the bottom. Use a #6 nut from the top to fasten the screw to the circuit board.
   Repeat for the remaining holes in the circuit board.



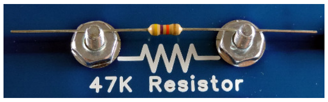
Assembly Continued

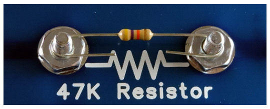
5. Assemble the coil.
   Items used: 1 - Ferrite Loopstick Antenna, 2 - Coil Clamps, 2 - #6 Washers, 2 - #6 Nuts.
   Locate the Coil location on the circuit board. Place the solder lugs over the screws at the end of the Coil symbol. Slide a coil clamp over each end of the ferrite rod. Place the coil clamp over the solder lug and secure with a #6 washer and #6 nut at each end.
   Double check that the coil is between the coil clamps and that the wires are not being pinched by the coil clamp.

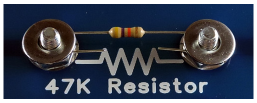


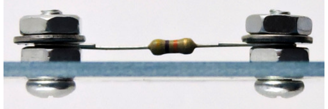


6. Assemble the 47K resistor
   Items used: 1 - 47K Resistor, 2 - #6 Washers, 2 - #6 Nuts.
   Locate the 47K Resistor location on the circuit board. Place the resistor across the nuts. Bend each end of the wire around the screw. Place a #6 washer and #6 nut on top of the wire. Tighten the nut to secure the resistor.



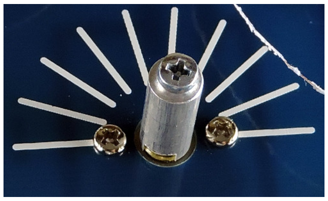


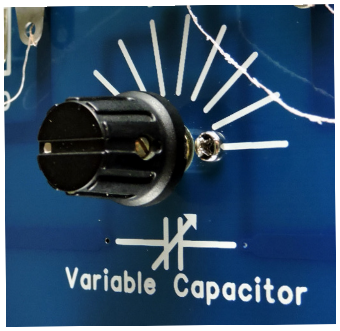




7. Assemble the .001uf Capacitor and 1N34A as described in Step 6 above.

8. Assemble the Knob.
   Attach the Knob shaft using the knob shaft screw to the variable capacitor shaft on the top side of the circuit board. Tighten the shaft screw. Turn the knob shaft to the full left position. Loosen the set screw in the side of the knob. Slide the knob over the knob shaft. Align the dot on the top of the knob with the far left dial markings on the circuit board. Tighten the set screw. The dot on the knob should point to the circuit board markings from full left to full right of the knob rotation.





Assembly Continued

9. Attach the earphone.
   Items used: 1 - Ceramic Earphone.
   Locate the Fahnestock clips marked EAR. Push down on the fahnestock clip. Slide the end of the earphone wire through the opening. Release the fahnestock clip. Note: Do not clip the wire by the plactic coating. The bare metal portion of the wire must be clamped by the fahnestock clip.

Antenna

The bare end of the wire connects to the fahnestock clip marked ANT. The antenna wire should be placed as high as feasible. Run the antenna horizontal to the ground in as straight a line as possible. If there is not enough space to run the antenna in a straight line, the wire can be placed in an arc or loop shape as well. Experiment with the antenna placement and shape to achieve the best results.

Do not use the antenna outdoors during bad weather.

Ground

The use of a ground is optional. There are many options for connecting a ground. You can just lay the ground wire along the floor in the opposite direction from the antenna. You can connect the end of the ground wire to a metal object, like a metal desk. You can also connect the end of the ground wire to a physical earth ground if you have access to one. Some metal plumbing in a home may be physically earth grounded for example.

Congratulations! Your Crystal Radio is ready to use.

Use the tuning knob to locate local radio stations. Keep in mind that the crystal radio will only receive strong stations. Unlike a traditional battery powered radio, the power to drive the sound you hear is from the signal the antenna is able to pick up. Experiment moving the antenna to different locations to increase stations and/or volume.

If you have any questions at this stage, please refer to the photo on page 1 and double check any directions and photos applicable.

Jeffrey La Favre June 20, 2015

Crystal Radio Project

Radio receivers capture radio waves broadcast by radio stations and convert those waves into sound that you can hear. For this project you will construct a crystal radio, a simple type of radio receiver that does not require a battery or other power supply. A crystal radio operates only on power that it captures from the radio waves transmitted by the radio station.

The original crystal radios of the early twentieth century utilized special crystalline minerals as detectors, converting the radio waves into the audio signals that can be heard when connected to a headset. These naturally occurring special minerals act as diodes in the crystal radio circuit. Galena is one example of these special minerals (https://en.wikipedia.org/?title=Galena). A device called a "cat's whisker," a spring-loaded wire, is used with the crystal to make the crystal operate as a diode. It can be a tedious exercise to adjust the contact point between the crystal and the cat's whisker so that they operate together as a diode. And without careful handling of the radio, the adjustment can be lost, necessitating a repeat of the frustrating exercise of adjusting the cat's whisker.

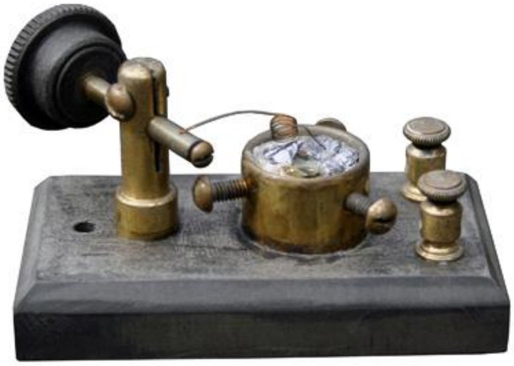


Figure 1 crystal and cat's whisker

With the availability of germanium and silicon-based diodes, it is no longer necessary to use crystals, but this type of radio is still called a crystal radio even when a natural crystalline mineral is not used as the detector. The term crystal radio is now used generally for any radio that operates only on power captured from the radio wave.

There has been a renewed interest in crystal radios over the past 15 years. Some Ham Radio operators have become interested in designing very efficient crystal radios, capable of receiving radio broadcasts from distances well exceeding 1,000 miles. There are contests for DX (distance) crystal radio operators. One contest winner, located in Hawaii, was able to hear a radio station in Cuba with his fancy crystal radio! Using the same radio you will build, I have been able to hear radio stations as far away as Georgia and Iowa, although I "cheated" by connecting an amplifier to my crystal radio (you have to give me a break, I don't hear very well anymore).

Radio waves are of the same class of radiation as light. Both are **electromagnetic radiation**. The distinguishing feature between radio waves and light is the **wavelength** of the radiation. Visible light, the kind humans can detect with their eyes, ranges in wavelength from 400 to 700 nanometers. A nanometer is one-billionth of a meter. Therefore, wavelengths of light are very short. Compared to visible light, the wavelengths of radio waves are very long. The shortest wavelengths of electromagnetic radiation that are considered radio waves are 1 millimeter in length and the longest are 100 kilometers in length (100 kilometers is equal to 62 miles). That is quite a large range in wavelengths.

History of Radio

James Clerk Maxwell, a Scottish physicist, established the theoretical basis for electromagnetic radiation in 1864 (https://en.wikipedia.org/wiki/James_Clerk_Maxwell). That year is a good starting point for this brief history of radio. Twenty-four years later, another physicist, Heinrich Rudolf Hertz, conducted experiments in transmitting radio waves through the air. He is generally credited with providing the experimental evidence for Maxwell's theory. The unit **Hertz** is used for the frequency of radio waves to honor the accomplishments of Heinrich Hertz (https://en.wikipedia.org/wiki/Heinrich_Hertz).

As the news of Hertz's experiments spread, a number of scientists and inventors began to experiment with radio waves. The most well-known was probably the Italian inventor, Guglielmo Marconi, who is credited with building the first successful wireless telegraphy system utilizing radio transmission through the air (https://en.wikipedia.org/wiki/Guglielmo_Marconi). His initial development work with radio waves occurred in the 1890's. By the middle of the decade, Marconi was able to transmit a radio signal up to a distance of 2 miles and over hills.

The signals transmitted by Marconi's equipment were in the form of Morse code, a series of short and long sounds heard as clicks or tones. In order to understand messages sent by this method, the listener needed to learn Morse code, not a trivial exercise. It was desired that the human voice could be transmitted by radio waves so that this technology could be of use to more people. This was accomplished in 1900 by a Brazilian priest named Roberto Landell de Moura.

During the period of 1900 to about 1920, radio grew from a curiosity to a powerful means of communication. At the end of this period, commercial radio stations began broadcasting programming to thousands of listeners. Station 8MK (now known as WWJ) claims to have broadcast the first radio news program on August 31, 1920, from Detroit, Michigan. During this time in radio history many people used crystal radios to listen to these early broadcasts.

The decades of 1920, 1930 and 1940 are often referred to as the **Golden Age of Radio** (https://en.wikipedia.org/?title=Old-time_radio). During the 1950's television replaced radio as the dominant form of news and entertainment delivered electronically. It is important to understand that television broadcasts also utilize radio waves for transmission. Television is a more complex system than radio and was therefore developed after radio.

Crystal radios are very simple in design and construction and were fairly cheap to buy during the 1920's. At the time most people could not afford the expensive radios that utilized vacuum tubes to amplify the sound. In fact, crystal radios are so simple in construction that some people built their own, saving even more money. In this project you will see that building a crystal radio is fairly easy. In addition, you will discover the disadvantages of a crystal radio, which soon caused them to fall from favor with the public when the cost of better radios became affordable (https://en.wikipedia.org/wiki/History_of_radio).

Wavelength and Frequency

There are various ways to characterize radio waves. I have already mentioned wavelength. Perhaps the easiest way to think about radio waves is to imagine that they look like water waves. Of course they are not water waves, this is just a convenient way to think about something we can't see with our eyes. If you drop a stone in a pool of water, a series of waves move across the surface of the water away from the location where the stone entered the water. In a similar manner we can imagine radio waves radiating away from the radio station transmitting antenna. For the water waves we can see that there are places we can name the tops of the waves and there are places we can name the bottoms of the waves. If we measure the distance between the top of one wave and the next, then that is the wavelength. We can also measure the distance from the bottom of one wave to the bottom of the next wave. That will also be the wavelength and will be the same length measured from the top of one wave to the next. In fact, we can measure the wavelength from any position of the wave to the next exact same position.

In the case of radio waves, we don't have a way to actually see them, but we can use instruments to measure the wavelength. In fact, it may be more convenient to use another measure of a radio wave, **frequency**. Frequency is the number of waves that pass a specific point in space within a specified time (usually one second). If we count just one wave passing a measurement point in one second, the frequency is one cycle per second or one H**ertz (Hz).**

Radio waves travel at the same speed as light through air, because they are both electromagnetic radiation. From the work of the famous physicist, Albert Einstein, we know that the speed of light is the ultimate speed limit in the Universe, nearly 300,000 kilometers per second (to be more accurate, 299,792.458 kilometers per second in a vacuum*, i.e.,* in space – in the Earth's atmosphere the speed is slightly slower, about 299,700 kilometers per second).

Suppose we set up an experiment where we could make light circle the Earth at its equator. The circumference of the Earth at the equator is 40,074 km. How many times would the light circle the Earth in one second? The light would travel 299,700 km, or more than 7 times around the Earth in one second (299,700 km/40,074 km = 7.479)!

If we know the frequency of a radio wave, then we can calculate the wavelength. This is possible because we know the velocity of electromagnetic radiation in air (299,700 km/sec or 299,700,000 m/sec). Suppose we measure a radio wave with an instrument and determine the frequency to be 1,100 kHz (1,100,000 Hz). That just happens to be the frequency broadcast by a strong AM radio station in Cleveland, which you will be able to hear with your crystal radio.

What is the wavelength of a 1,100 kHz radio wave? In one second we know the radio wave travels 299,700,000 meters through air. And during that time 1,100,000 waves will pass an observation point. If we could count the number of waves along a distance of 299,700,000 meters, we would count 1,100,000 waves. Therefore, the length of one wave would be 299,700,000 m / 1,100,000 waves = 272 meters per wave (or wavelength). The wavelength of a radio wave of 1,100 kHz frequency is 272 meters.

Amateur radio operators, also known as Ham Radio operators, have permission to transmit radio within a number of radio bands, or small ranges of frequencies. These bands are often referred to by the wavelength in meters. For example, there are amateur bands at 40, 80 and 160 meters wavelength, as well as other bands.

If you want to design a radio to capture a radio broadcast, then it is important to know both the frequency and the wavelength of the radio waves. This will help you design the tuning circuit and antenna required for good reception. For example, a good antenna design is achieved with a long wire, divided in the middle, with a total length of one-half the wavelength of the radio wave. This kind of antenna is named a dipole. There are also other types of antennas that perform well.

In designing the tuning circuit of a radio, it is important to know the frequencies of the radio stations you wish to tune. For example, in the United States, AM radio stations broadcast on frequencies ranging from 540 to 1,610 kHz. If you are listening to a radio station and hear the announcer say: “This is WTAM 1100” then you can understand that the station named WTAM is broadcasting at a frequency of 1,100 kHz.

You will begin your construction of the crystal radio by winding two coils of wire around pieces of plastic pipe. These become the **inductors** of your radio. An inductor is a new category of electronic component that you have not worked with before, but is a very important type of component.

You have already learned about capacitors and have even made a capacitor from aluminum foil and polyethylene sheet for insulation. Recall that capacitors can store electrical energy. This is done by collecting positive and negative charge on the opposing plates of the capacitor, which creates an electric field. Energy is contained in the capacitor by the created electric field.

In some ways an inductor is similar to a capacitor. Inductors can also store electrical energy. In the case of an inductor, the energy is stored in a **magnetic** field. Capacitors store energy in an electric field and inductors store energy in a magnetic field.

When a capacitor is paired with an inductor, a very useful circuit can be designed to tune a specific frequency of radio waves. This circuit is sometimes called a **LC circuit** or **tank circuit**. In the case of the word “tank,” we can think of it as a container for the specific frequency of radio waves. The letters **L** and **C** represent inductance and capacitance. The letter C is obvious but not the letter L. The letter L represents inductance in electrical equations and the unit used is the **Henry**. The inductance of a coil of wire can be measured in Henries. You have already learned that the unit of capacitance is the Farad, and hopefully remember that a one Farad capacitor is a very large capacitor. The same can be said for an inductor. A one Henry inductor is a very large coil of wire. In the case of our crystal radio, it is more convenient to measure the inductance in units of microhenries (µH). There are one million microhenries to one Henry.

The Henry is defined as follows.

> *In an inductor, if the current is changing at a constant rate of one ampere per second, a one Henry inductor will generate a one volt potential difference across the inductor.*

That may be more difficult to understand than the definition of a Farad for capacitance. All you really need to understand is that inductors can store electrical energy in a magnetic field and we can measure the storage capacity in terms of the unit called a Henry.

Capacitors and inductors behave differently when voltage is applied across them. It is this difference that makes them a good pair in a tuning circuit. When voltage is applied across a capacitor, at first, high current flows into the capacitor. As the current charges the capacitor, voltage across the plates rises, which causes a back voltage, reducing the current flow. The exact opposite happens with an inductor. When voltage is first applied to an inductor, there is a nearly instantaneous build-up of back voltage, resulting in a very low initial current flow. As time goes on, the back voltage decreases and the current flow increases, just the opposite of a capacitor. These two behaviors, that complement each other, provide a good tuning circuit. With an inductor of a specific value paired to a capacitor of a specific value, the circuit containing them will allow the **resonance** of only a small range of radio frequencies. This is one method for tuning radios to a specific frequency. By adjusting the value of either the inductor or capacitor (or both), it is possible to change the frequency of resonance in the circuit. In radios it is more common to use an adjustable capacitor to change the tuning. By adjusting the capacitor, different radio stations can be tuned.

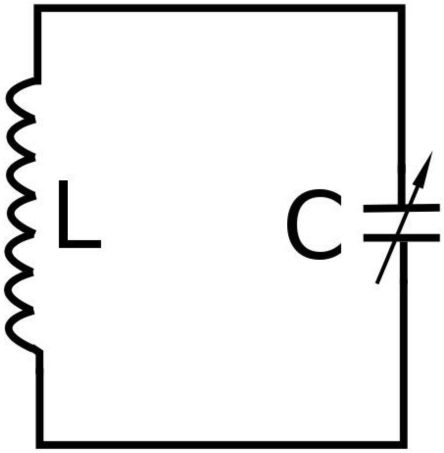

Figure 2 Schematic of an LC circuit

Figure 2 shows the schematic of a LC circuit of the same type you will construct for your crystal radio project. Antenna and ground connections can be added to the circuit (for example connect antenna to top wire between coil and variable capacitor and ground wire to bottom wire between coil and variable capacitor). A connection for a "detector" can be added into the circuit as well. The detector extracts the sound signal from the radio waves. Another way to connect antenna and ground is by the "loose coupling" of another coil. That is the method you will use. The radio signal is transferred from the antenna coil to the coil of the LC circuit without any wire connection. This is made possible by the sharing of a magnetic field between the two coils.

All of these additions can make the circuitry more difficult to understand, so I have just provided you with the tank circuit in Figure 2. Radio signals delivered to the tank circuit from the antenna are in the form of **alternating current**, similar to the current found in your house electrical wiring. The difference is one of frequency. House current has a frequency of 60 Hz, while radio frequencies are much higher (for example, our radio station AM 1100, which has a frequency of 1,100,000 Hz). The purpose of the tank circuit is to provide a resonating circuit for the alternating current of a specific frequency (a specific radio station). At the tuned frequency, the current will make one cycle of traveling first one direction and then the other, matched to the frequency. It is the job of the LC circuit to capture radio waves of a specific frequency and rejecting radio waves of other frequencies. Otherwise, we would have to listen to many stations at one time, talking over each other.

Imagine that we had a circle of wire, cut in one place by inserting a magic mirror. The job of the magic mirror would be to reflect the current flowing in the circuit so that it bounces back and forth, like alternating current. Now suppose the length of the wire is 136 meters (half of 272 meters, the wavelength of a radio wave at a frequency of 1100 kHz). The current in the loop would be in resonance (tuned) to a frequency of 1100 kHz.

Well, we don't have a magic mirror to bounce the current back and forth. Even if we did, having to make a circle of wire 136 meters long would not be very practical. But what if we put a capacitor and an inductor in our circular circuit? The capacitor cuts the circuit, just like our magic mirror. Then we can make a compact circuit that will resonate at the desired frequency. It takes time for the capacitor to charge and discharge, allowing current to flow for a relatively long period of time even in a circuit of short length. The inductor reduces the current flow in the circuit to insure that the current will flow for the proper amount of time to make the circuit resonant. By adjusting the capacitance and inductance of the circuit, current will cycle back and forth at a rate to match a specific frequency. By adjusting the value of a variable capacitor, it is possible to change the frequency of resonance within a certain range. The current cycles back and forth at the same rate as the frequency of the tuned radio signal.

Understanding resonance in an electrical circuit can be difficult. Think about a child on a swing who is being pushed by a parent. Every time the swing comes back, just at the right moment, when the movement backwards stops, the parent gives a push forward to the child. This keeps the child swinging. This is like a resonating circuit. Now suppose the parent gave a push to the child while the swing was still moving backward. That would have a braking effect on the swinging, and with each cycle the swinging would be less and less. This would be the same as a circuit that was not resonant.

Keep in mind that the antenna of a radio intercepts radio waves at many different frequencies. It is the job of the tuning circuit to select a narrow range of frequencies (hopefully just one radio station) and reject all other frequencies. Only the frequencies that resonate well in the tank circuit will be heard. The energy of non-resonant frequencies will be absorbed by the tank circuit and not passed on through the radio.

We would like our crystal radio to tune all of the AM broadcast band, so that we can listen to various AM radio stations. The FCC, an organization that governs radio in the United States, has set the range of frequencies for the AM band (540 to 1610 kHz). You can search for licensed radio stations at their web site where you will also find technical information such as location of the transmitting antenna and the amount of electrical power used in transmitting the signal https://www.fcc.gov/encyclopedia/am-query-broadcast-station-search

This information can be helpful to you while using your crystal radio. Remember, your radio operates only on the power transmitted by the radio station. A station that is close by or one that uses a high amount of power will be easier to hear.

Calculating the Resonant Frequency of a LC circuit

Suppose for a minute that you are assigned to design your own crystal radio. You have the basic knowledge regarding how a LC circuit is constructed (see Figure 2). However, you don't know how many turns your coil should have or what the capacitance range should be for the variable capacitor. There are two formulas that you can use to help with the design of the LC circuit. It is possible to make your own variable capacitor, but most people elect to buy a manufactured one. The capacitor you will use has an adjustable capacitance range of about 25 to 400 pF (0.000025 to 0.000400 µF) which is commonly used for tuning radio frequencies in the AM band. Now that we have established the capacitance, we need to calculate the amount of inductance needed in the coil. The lowest frequency we wish to tune is 540 kHz. Just to make sure our radio will tune this frequency, we can design for a slightly lower frequency, say 538 kHz. We can use a formula to calculate the required inductance. Our formula requires the frequency to be in MHz, not kHz, so we divide 538 kHz by 1,000 to convert to 0.538 MHz. Now we can use the formula below to calculate the required inductance.

Formula for calculating inductance

$$L = \frac{1}{C(2\pi f)^2}$$

where L is the inductance of the coil in microhenries (µH)
f is the frequency in MHz
C is the capacitance of the capacitor in microfarads (µF)

The lowest frequency tuned will be when the capacitor is adjusted to the highest capacitance.

Step one: multiply the frequency by 2π: 6.283 X 0.538 MHz = 3.380

Step two: square the result of step one (i.e., multiply it by itself): 3.380 X 3.380 = 11.42

Step three: multiply the result of step two by the capacitance: 11.42 X 0.000400 µF = 0.004568

Step four: divide 1 by the result of step three: 1/0.004568 = 219 µH

Our coil should have an inductance of 219 microhenries. We can just round that off to 220 microhenries.

If we use a 220 µH coil, then what will the highest frequency tuned be? To make that calculation we can rearrange the formula to this:

$$f = \frac{1}{2\pi\sqrt{LC}}$$

The highest frequency tuned will be when the capacitor is adjusted to the lowest capacitance.

Step one: multiply the inductance by the capacitance: 0.000025 µF X 220 µH = 0.0055

Step two: take the square root of the product of step one: sqrt 0.0055 = 0.07416

Step three: multiply the result of step two by π: 3.142 X 0.07416= 0.2330

Step four: multiply the result of step three by 2: 2 X 0.2330 = 0.466

Step five: divide 1 by the result of step five: 1/0.466 = 2.15 MHz or **2,150 kHz**

Therefore, we can expect our radio to tune from 538 kHz to 2,150 kHz if we use a 220 µH coil, more than enough to cover the AM broadcast band.

Now we need another formula to help us construct a 220 µH coil:

$$L = \frac{(d^2 n^2)}{18d + 40I}$$

where L = the coil inductance in microhenries
d = the diameter of the coil in inches
n = the number of turns of the coil
I = the length of the coil in inches

You will wind 22 gauge magnet wire around a piece of PVC pipe to make the coil. The outside diameter of the pipe is 3.5 inches. Technically, we should add the diameter of the wire to the diameter of the pipe, but we will not do this because the wire diameter is very small compared to the pipe diameter (the value d is the diameter of the coil, from the center of the wire thickness on one side of the coil to the center of the wire thickness on the opposite side of the coil).

There are three independent variables in the formula above (d, n and I) that we must know in order to calculate the inductance. We already know the diameter (d), which leaves two independent variables. It would be helpful if we could establish the value of one more independent variable. What we really want to know is the number of turns required for the coil. Therefore, we need to know the value for I, the length of the coil. We are using 22 gauge wire, which has a diameter of 0.0253 inches. But that does not account for the thin coating of enamel used for insulation or the small amount of space between windings that usually occurs when winding the coil. When I wound the wire around the pipe, I found that each turn of the coil had a width of 0.0278 inches. We can use that number to calculate the length of the coil (I). We will use an iteration process to find the number of turns of wire required for a 220 µH coil. Suppose we start by finding the inductance of a coil with 40 turns:

$$L = \frac{3.5^2 x\, 40^2}{(18\, x\, 3.5) + (40\, x\, 1.11)}$$

If we have a coil of 40 turns, the length of the coil will be 0.0278 inches X 40 = 1.11 inches, the value of l.

By solving the above equation we find that a coil of 40 turns will have an inductance of 182 µH. We need a coil with 220 µH inductance, so it will need more than 40 turns. Let us try 45 turns:

$$L = \frac{3.5^2 x\, 45^2}{(18\, x\, 3.5) + (40\, x\, 1.25)}$$

A coil with 45 turns will be 45 X 0.0278 inches = 1.25 inches long. When we solve the above equation we find that a coil of 45 turns will have an inductance of 220 µH. Perfect! Our coil must have 45 turns to create an inductor with 220 µH. Now you are ready to make your coil!

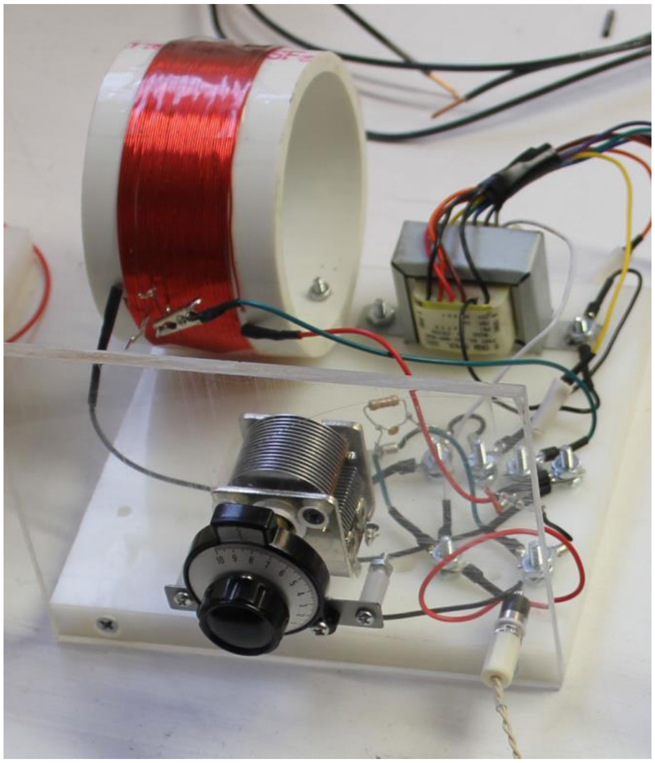

Figure 3 Crystal Radio

Crystal Radio Project

Figure 3 is a photo of the main part of the crystal radio that you will construct. The coil constructed with red wire is located at the back of the radio on the left side. The variable capacitor is located at the front of the radio and has a knob attached for adjusting the capacitance. You should notice that there are some more parts of the radio. You will learn about these in subsequent lessons.

Winding the tuning coil

In order to facilitate your project, I have already cut the wire for the coil for you. I made some calculations and measurements first. Your coil will contain two sections, one of 28 turns and one of 17 turns (45 turns total). You will construct a "tap" where the two coil sections meet. In this case the detector of your radio will be connected to this tap (I will explain why later).

You will use 22 gauge magnet wire for the coil. This wire has a very thin coating of enamel (paint) for insulation. The insulation is needed to prevent shorting of the coils since the turns of wire will touch each other when you tightly wind the coil. The diameter of 22 gauge wire is 0.0253 inches, which will be a factor in calculating the amount of wire needed to make one turn on the pipe. To get a good estimate of the wire needed for one turn, we can add the diameter of the wire to the diameter of the pipe: 3.5" + 0.0253" = 3.5253". Then we can multiply the diameter by pi to find the circumference, which is the same as the length of wire needed: π X 3.5253" = 11.075". I tried another method to determine the amount of wire needed for one turn. I actually wrapped a piece of wire around the pipe and cut it carefully so that the amount of wire was just enough to make one turn. I measured this amount of wire and found it was about 11 3/32" long, which is the same as 11.094" long. My calculated value was 11.075" and the actual measurement was 11.094". There is not much difference between these two, but we should use the larger number so that we will have enough wire. You will need to have some extra wire at the ends of the coil to make connections so we will add 2 extra inches.

28 turn coil: 28 turns X 11.094 inches = 310.63 inches + 2 inches = about **312.5 inches**

17 turn coil: 17 turns x 11.094 inches = 188.60 inches + 2 inches = about **190.5 inches**

Before you start winding wire on the pipe, you need to remove the enamel insulation from the four ends of the two pieces of wire. You can do this with a piece of sandpaper. The insulation is red colored, so you should be able to tell when it has been removed. Make sure you remove ALL insulation for a length of about one inch from the end of the wire. If you leave some insulation on the wire, you may not be able to solder connections later (solder won't stick to the enamel insulation).

I have already drilled holes in the coil form (pipe) for mounting the coil on the radio base and for inserting the ends of the wire. At each end of the 45 turns of wire, the wire is threaded into a hole in the pipe and then back out through another hole near the first hole (make sure you use the holes that are paired, not the single holes that will be used to mount the coil). After you have threaded one end of the wire through the holes, so that about ½ inch of the wire end is protruding from the pipe, start wrapping the wire around the coil core (Figure 4). To do this, hold the pipe with threaded wire end to the right (Figure 4). The wire that you are wrapping around the pipe should sit on the top side of the pipe and you should rotate the pipe toward you (make the top side of the pipe rotate toward you). While you are wrapping the wire, place your thumb on top of the wire and apply some pressure. This will keep the wire windings tight. After you have a few turns done, make sure that the turns of wire are all touching (squeeze them together if there is space between the wire coils). The turns of wire should be tight in each wrap and also right next to each other.

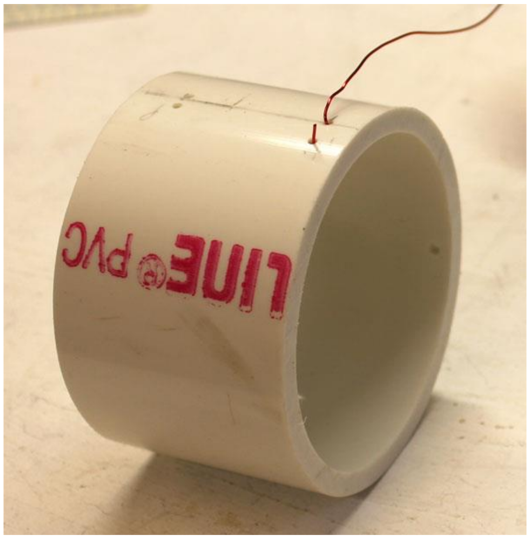

Figure 4 preparing the coil form for winding

After you have wrapped the 312.5 inches of wire around the pipe 28 turns, you should have about one inch of wire remaining. Using some packing tape, tape down the coil to prevent it from unwinding.

Take one end of the 190.5 inch piece of wire and twist it with the end of the wire you just coiled on the pipe. The length of the twisted part should be about ¼ inch. This will form the tap on your coil. If a soldering iron is available, solder the twisted wires together. The twisted wires should point out from the coil so that you can attach a wire later.

Continue wrapping the coil in the same direction. The second piece of wire should be enough to make an additional 17 turns. After you have made 17 turns past the tap, there should be very little wire left. If there is not enough wire to reach the pair of holes on the pipe, then unwind the coil by one turn. If you unwind one turn there will be plenty of extra wire. It will not make much difference if the coil has 44 or 45 turns, just a slight difference in the tuning range. Thread the wire end through the two holes on the pipe as provided, just as you did for the start of the coil. Make sure the wire of the last coil is tight after you thread the wire through the holes so that the coil does not loosen up. You can apply a couple of pieces of clear packing tape over the wire coils to keep them from spreading across the pipe. It is best if you can't see the white color of the pipe between the turns of wire. Or at least keep the open space between turns to a minimum. Congratulations! You have finished wrapping your tuning coil. Construction of the remainder of your radio will be covered in other lessons soon to follow.

SIMPLE CRYSTAL RECEIVING SETS

AND HOW TO MAKE THEM

EDITED BY
BERNARD E. JONES
Editor of "Amateur Wireless," etc. etc.

WITH 114 ILLUSTRATIONS

CASSELL AND COMPANY, LTD
London, New York, Toronto and Melbourne

PREFACE

THIS Handbook deals, in a simple, straightforward manner, with the making of a number of different kinds of crystal sets representative of those in present-day use. It is uniform in style and price with other members of the "Amateur Wireless" Handbook Series, notably with two of them, namely "Wireless Component Parts and How to Make Them" and "Simple Valve Receiving Sets and How to Make Them," the former containing detailed instructions on the making of the various components forming part of many kinds of wireless receiving apparatus, and the latter treating of valve sets in exactly the same way as crystal sets are dealt with in this present Handbook.

This book has been compiled from the pages of "Amateur Wireless," the well-known weekly journal for wireless amateurs, and the name of the author responsible for each of the various chapters is given in many cases immediately below the chapter heading.

It is believed that the information is presented in such simple fashion as not to cause the reader any trouble when putting it into practice, but should he be in difficulty with regard to any matter dealt with in this book, or to any other subject within the scope of the weekly journal mentioned, he should send a query to "Amateur Wireless," La Belle Sauvage, London, E.C.4, *but should take particular care to accompany his query with a stamped and addressed envelope and a coupon from the current issue of that journal.*

THE EDITOR.

SIMPLE CRYSTAL RECEIVING SETS AND HOW TO MAKE THEM

CHAPTER I

A Simple and Efficient Receiving Set

As the result of recent experiments conducted in the United States of America to produce an efficient crystal receiving set that at the same time would be reasonably simple and inexpensive to make, a circular was issued by the American Bureau of Standards giving constructional details of a set evolved in accordance with the result of those experiments. The set, it is

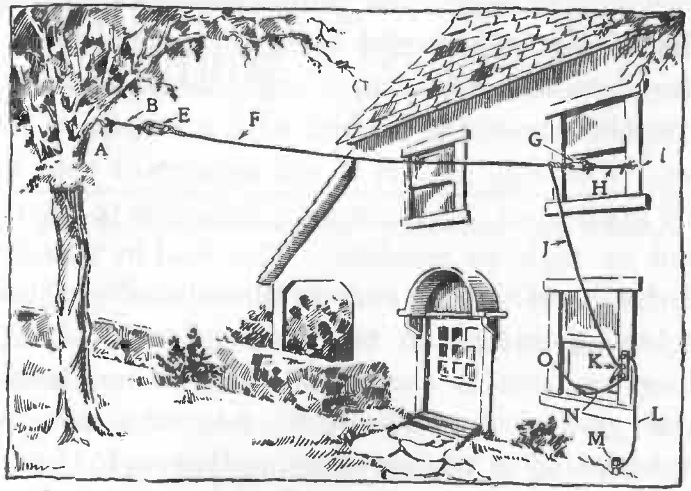

Fig. 1.—General View of the Aerial and its Supports and Connections.

thought, forms a fitting introduction to this book. It has been made by thousands of people, including hundreds of readers of "AMATEUR WIRELESS," and its efficiency is well proved by ample practical experience.

Elements of the Set.—In this receiving set there are five essential parts: the aerial, lightning switch, ground or earth connection, tuner and detector, and telephone receivers, and the construction of each (excluding the last-named, which, of course, must as a rule be purchased) is described under its proper heading.

The details regarding the aerial and earth hold true for any set, but it must be remembered that the aerial, both as regards type and system of erection, is largely dependent upon individual circumstances.

The Aerial.—The aerial is simply a wire suspended between two elevated points, and should not be less than 30 feet above the ground with a length of about 75 feet. (See Fig. 1.) It is not important that it be strictly horizontal. It is, in fact, desirable to have the far end as high as possible. The lead-in wire from the aerial itself should run as directly as possible to the lightning switch. If the position of the adjoining buildings or trees is such that the distance between them is greater than about 85 feet, the aerial can still be held to a 75-foot distance between the insulators by increasing the length of the piece of rope (B) to which the far end is attached. The rope (H) securing the aerial insulator to the house should not be lengthened to overcome this difficulty, because by so doing the lead-in wire (J) would be lengthened.

The parts will be referred to by reference to the letters appearing in Figs. 1 and 2.

A and I are screw eyes sufficiently strong to anchor the aerial at the ends. B and H are pieces of rope $\frac{3}{8}$ in. or $\frac{1}{2}$ in. in diameter, just long enough to allow the aerial to swing clear of the two supports. B is a piece of $\frac{3}{8}$-in. or $\frac{1}{2}$-in. rope sufficiently long to make the distance between E and G about 75 feet. A single-block pulley may be used, but is not really essential.

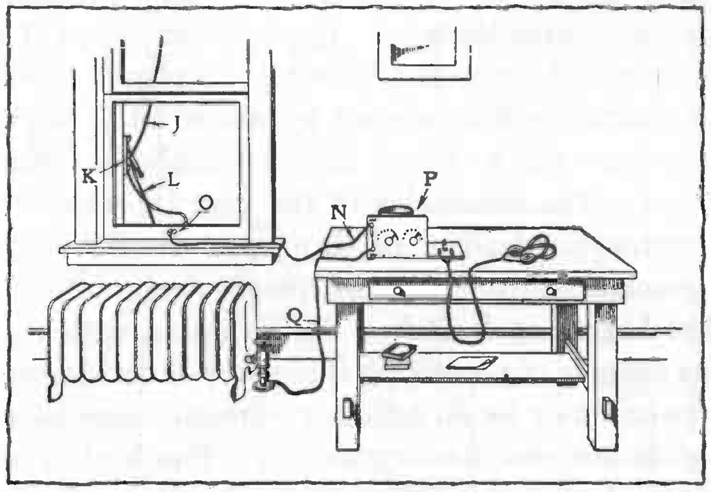

Fig. 2.—The Receiver and its External Connections.

E and G are two insulators which may be constructed of any dry hardwood of sufficient strength to withstand the strain of the aerial; blocks about $1\frac{1}{2}$ in. × 2 in. × 10 in. will serve. The holes should be drilled, as shown in Fig. 1, sufficiently far from the ends to give proper strength. If wood is used the insulators should be boiled in paraffin wax for about an hour. If porcelain wiring cleats are available they may be substituted instead of the wood insulators. If any unglazed porcelain is used as insulators, it should be boiled in paraffin wax in the same way as the wood. The wire for the aerial may be No. 14 or 16 copper wire either bare or insulated. The end farthest from the receiving set may be secured to the insulator (E) by any satisfactory method, care being taken not to kink the wire. Draw the other end of the wire through the other insulator (G) to a point where the two insulators are separated by about 75 ft.; twist the *insulator* (G) so as to form an anchor as shown in Fig. 1. The remainder of the wire (J) which now constitutes the lead-in or drop-wire should be just long enough to reach the lightning switch.

The Lightning Switch.—The lightning switch K is for the purpose of protecting the system from lightning. This switch may be an ordinary porcelain-base, single-pole double-throw battery switch. The lead-in wire (J) is attached to this switch at the middle point. The switch blade should always be thrown to the upper clip when the receiving set is not actually being used and to the lower clip when it is desired to receive signals.

The Earth Lead.—L is the earth wire for the lightning switch; it may be a piece of the same wire as used for the aerial, of sufficient length to connect the upper clip of the lightning switch (K) to the clamp on the earth rod (M), which is a piece of iron pipe or rod driven 3 ft. to 6 ft. into the ground, preferably where the ground is moist, and extending a sufficient

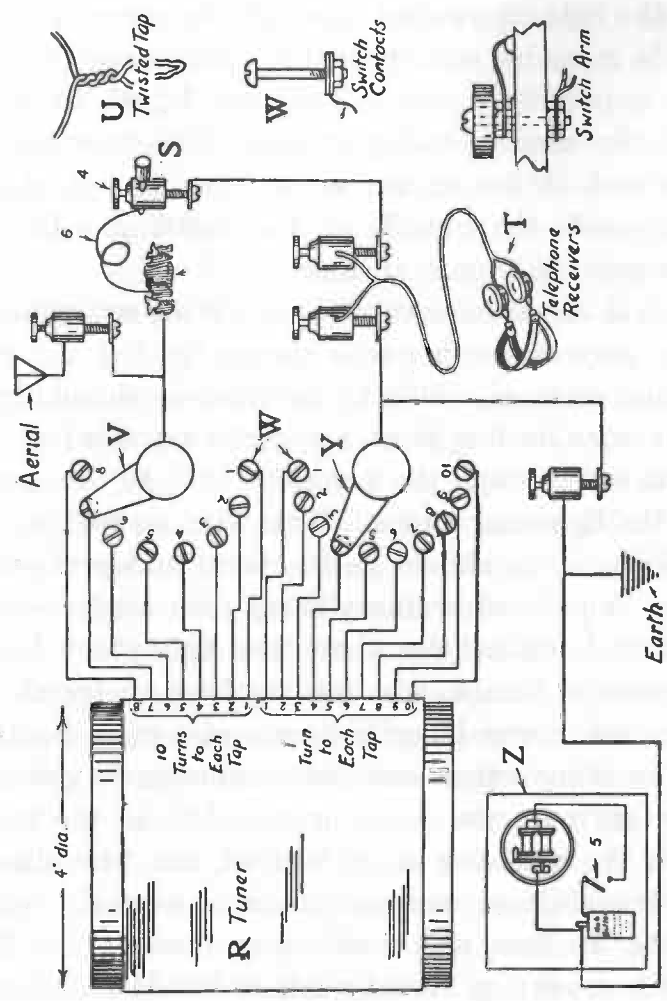

Fig. 3.—The Receiving Set in Complete Detail.

distance above the ground in order that the ground clamp may be fastened to it.

The Lead-in.—N is a wire leading from the lower clip of the lightning switch through the porcelain tube (O) to the receiving set terminal marked aerial (Fig. 3).

O is a porcelain tube of sufficient length to reach through the window casing or wall. This tube should be mounted in the casing or wall so that it slopes down towards the outside of the building. This is done to prevent ingress of rain.

General Arrangement.—The receiving set installed in some part of the house is shown by Fig. 2. P is the actual receiver, which is described in detail later. N is the wire leading from the aerial terminal of the receiving set through the porcelain tube to the lower clip of the lightning switch. This wire, as well as the wire shown by Q, should be insulated and preferably flexible. A piece of ordinary hemp cord might be unbraided and utilised for these two important leads. Q is a piece of flexible wire leading from the receiving set terminal marked earth to a water-pipe, heating system or some other metallic conductor to ground. If there are no water-pipes or radiators in the room in which the receiving set is located, the wire should be run out of doors and connected to a special earth below the window, and which may consist of a few yards of wire netting buried a few inches deep in damp soil, or an iron rod as mentioned.

Crystal Detector.—The construction of a crystal detector (S, Fig. 3) may be very simple although quite satisfactory. The crystal, as it is ordinarily

purchased, may be unmounted or mounted in a little block of metal. For mechanical reasons the mounted type may be more satisfactory, but that is of no great consequence. It is very important, however, that a good crystal be used. It is probable also that a galena crystal will be the most satisfactory.

The crystal detector may be made up of a tested crystal, three wood-screws, a short piece of copper wire, a nail, setscrew type of terminal, and a wooden knob or cork. The crystal is held in position on the wooden base by three brass wood-screws, as shown in Fig. 4. A bare copper wire may be wrapped tightly round the three brass screws for contact. The assembling of the rest of the crystal detector is quite clearly shown in Fig. 4. If, however, the reader wishes to adopt any other type of detector, he will find almost every type illustrated and explained in "Wireless Component Parts, and How to Make Them," uniform in style and price with the present volume.

Telephones.—It is desirable to use a pair of telephone receivers connected by a head band, usually called a double telephone head-set (T, Fig. 3). The telephone receiver may be of any of the standard commercial makes having a resistance of between 2,000 and 3,000 ohms. The double telephone receivers will cost more than all the other parts of the station combined, but it is desirable to get them, especially if one intends to improve the receiving set later. A single telephone receiver with a head band may be used, though it gives results somewhat less satisfactory.

Accessories.—Under the heading of accessory equipment may be listed terminals, switch-arms, switch-contacts, test-buzzer, dry battery, and boards on which to mount the complete apparatus. The terminals, switch-arms and switch-contacts may all be readily purchased. There is nothing peculiar about the pieces of wood on which the equipment is mounted, except that they should be soaked in melted paraffin wax for an hour or two.

Winding the Tuner.—Having obtained a piece of cardboard tubing 4 in. in diameter and about $\frac{1}{2}$ lb. of No. 24 (or No. 26) d.c.c. copper wire, start the winding of the tuner (see R, Fig. 3). Punch two holes in the tube about $\frac{1}{2}$ in. from one end, not shown in the diagram. Weave the wire through these holes in such a way that the end of the wire will be quite firmly anchored, leaving about 12 in. of the wire free for connections. Start with the remainder of the wire to wrap the several turns in a single layer about the tube, tightly and closely together. After ten complete turns have been wound on the tube, hold those turns snugly while a tap is taken off. This tap is made by forming a 6-in. loop of the wire and twisting it together at such a place that it will be slightly staggered from the first tap. This method of taking off taps is shown quite clearly at U (Fig. 3). Proceed in this manner until seven twisted taps have been taken off at every ten turns. After these first seventy turns have been wound on the tube, then take off a 6-in. twisted tap for every succeeding single turn until ten additional turns have been wound on the tube.

After winding the last turn of wire, anchor the end by weaving it through two holes punched in the tube, much as was done at the start, leaving about 12 in. of wire free for connecting. It is to be understood that each of the eighteen taps is slightly staggered from the one just above, so that the several taps will not be bunched along one line on the cardboard tube.

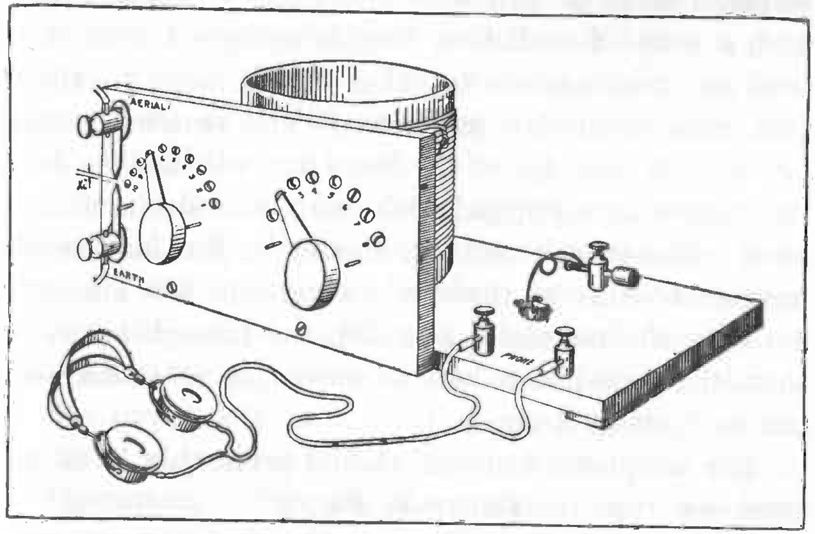

Fig. 4.—View of the Receiver.

It will be advisable, after winding the tuner, to dip it in hot paraffin wax.

Upright Panel and Base.—Having completed the tuner to this point, set it aside and construct the upright panel shown in Fig. 4. This panel may be a piece of wood approximately $\frac{1}{2}$ in. thick. The positions of the several holes for the terminals, switch-arms and switch-contacts may first be laid out and drilled. The aerial and earth terminals may be ordinary $\frac{1}{8}$-in.

brass screws of sufficient length and supplied with three nuts and two washers. The first nut binds the bolt to the panel, the second nut holds one of the short pieces of stiff wire, while the third nut holds the aerial or earth wire, as the case may be. The switch-arm with knob (shown in Fig. 3) may be purchased in the assembled form, or it may be constructed from a thin slice cut from a broom-handle and a bolt of sufficient length equipped with four nuts and two washers together with a narrow strip of thin brass somewhat as shown. The switch contacts (w, Fig. 3) may be of the regular type, or they may be brass bolts equipped with one nut and one washer each. The switch-contacts should be just sufficiently near each other so that the switch-arm will not drop between the contacts, but also far enough apart so that the switch-arm can be set so as to touch only one contact at a time.

The telephone terminal should preferably be of the set-screw type, as shown in Fig. 3.

Wiring.—Having constructed the several parts just mentioned and mounted them on the wood base, the next matter is to connect the several taps to the switch-contacts and attach the other necessary wires. Scrape the cotton insulation from the loop ends of the sixteen twisted taps as well as from the ends of the two single-wire taps coming from the first and last turns. Fasten the bare ends of these wires to the proper switch contacts as shown by the corresponding numbers in Fig. 3. Be careful not to cut or break any of the looped taps. It would be preferable to fasten the connecting wires to the switch-contacts by binding them between the washer and the nut, as shown at w (Fig. 3). A wire is run from the back of the terminal marked earth (Fig. 3) to the back of the left-hand switch-arm bolt (Y), thence to underneath the left-hand binding post marked phones in Fig. 4. A wire is then run from underneath the right-hand terminal marked phones to underneath the binding post w (Fig. 3), which forms a part of the crystal detector. Take a piece of No. 24 bare copper wire about 2½ in. long and twist one end tightly round the nail passing through binding post s; its other end will rest gently by its own weight on the crystal. The bare copper wire which has been wrapped tightly round the three brass wood-screws holding the crystal in place is led to and fastened at the rear of the right-hand switch-arm bolt (v), thence to the upper left-hand binding post marked aerial. As much as possible of this wiring is shown in Fig. 3.

Operation.—After all the parts of the set have been constructed and assembled the first essential operation is to adjust the little piece of wire, which rests lightly on the crystal, to a sensitive point. This may be accomplished in several different ways; the use of a miniature buzzer transmitter is very satisfactory. Assuming that the most sensitive point on the crystal has been found by the method described later, the rest of the operation is to get the set in resonance or in tune with the station from which one wishes to hear messages. The tuning is attained by adjusting the inductance of the tuner. That is, one or both of the switch-arms are rotated until the proper number of turns of wire of the tuner are made a part of the metallic circuit between the aerial and earth, so that, together with the capacity of the aerial, the receiving circuit is in resonance with the particular transmitting station. It will be remembered that there are ten turns of wire between each of the first eight switch contacts and only one turn of wire between each two of the other contacts. The tuning of the receiving set is best accomplished by setting the right-hand arm (v., Fig. 3) on contact (1) and rotating the left-hand switch-arm over all its contacts. If the desired signals are not heard, move the right-hand switch-arm to contact (2) and again rotate the left-hand switch-arm throughout its range. Proceed in this manner until the desired signals are heard.

The Test Buzzer.—As mentioned previously, it is easy to find the most sensitive spot on the crystal by using a test buzzer (z, Fig. 3). The test buzzer is used as a miniature local transmitting set. When connected to the receiving set, as shown at z, Fig. 3, the current produced by the buzzer will be converted into sound by the telephone receivers and the crystal, the loudness of the sound depending on what part of the crystal is in contact with the fine wire.

In order to find the most sensitive spot connect the test buzzer to the receiving set as directed, close the switch 5, Fig. 3, set the right-hand switch-arm on contact point No. 8, fasten the telephone receivers to the binding posts marked phones, loosen the set-screw of the binding post slightly and change the

position of the fine wire (6, Fig. 3) to several positions of contact with the crystal until the loudest sound is heard in the 'phones, then tighten the binding post set-screw (4) slightly.

The illustrations to this chapter were published by " Popular Radio " and prepared by them from the drawings issued by the U.S.A. Government, and the Editor of the present Handbook wishes to express his indebtedness for their use to the American publication named.

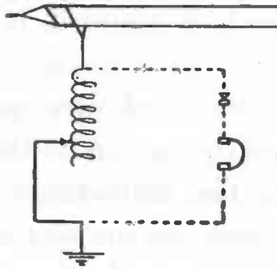

Fig. 5.—Diagram of Oscillatory Circuit.

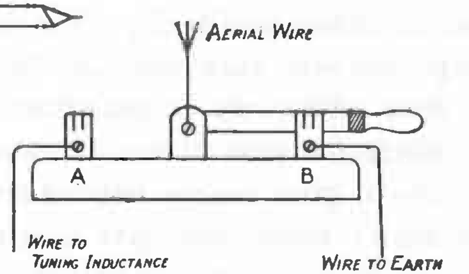

Fig. 6.—Details of Lightning Switch and Connections.

The Range of the Set.—It is impossible to state offhand what the range of a set will be, for there are different factors that govern the operation. Briefly these are as stated below :

(1) The distance of the transmitting station and its direction.

(2) The power used by the station ; this, of course, varies enormously.

(3) The height and length of the receiving aerial.

(4) The position of the receiving station. If it is on a hill or a level plain, and is not sheltered by trees

or neighbouring houses, these conditions confer great advantages.

(5) The efficiency of the receiving set. This depends on (*a*) good insulation, (*b*) proper adjustment of detector, and (*c*) good telephones.

Hints on Operation.—In order that signals may be received, it must be remembered that the receiving set must be in " tune " with the vibrations in the ether set up by the transmitting station. To tune-in stations of different wave-lengths either the inductance or capacity, or both, of the oscillatory circuit (see Fig. 5) must be altered. The method adopted in a simple set is to vary the inductance.

Now inductance necessitates a length of wire, preferably in the form of turns ; two turns, provided they are close, give nearly four times the inductance of one turn ; three turns give nine times the inductance, and so on. Also the inductance increases in proportion to the square of the diameter of the turns in the same way. By having, say, 100 turns of wire in a former (each turn being close to its neighbour but well insulated from it), and having a slider, we can vary the inductance over a wide range, increasing by a single turn at a time. The slider has certain disadvantages. It wears the wire by constant rubbing and is liable to short-circuit two or more turns, which will waste some of the energy. In order to overcome these objections, and also to make an inductance suitable for panel mounting, the turns are brought out to two switches, one called the " tens switch " and the other the " units." Each stud on the tens switch

has ten complete turns connected to it, so that by moving the knob of this switch the inductance is varied by comparatively large amounts at a time. To tune more closely the units switch is used, ten studs being connected to the last ten turns on the coil.

By using both switches together it is possible to include any number of turns varying from one to the greatest number on the coil.

The lightning switch is shown enlarged by Fig. 6. A single-pole change-over switch is used. The aerial wire is connected to the arm. The lead to the tuning inductance is connected to A and the earth wire to B. When the set is in use the switch should be over to the left (A), and when out of use it should be over to the right (B), thus earthing the aerial.

CHAPTER II

A Single-slider Set

By PAUL D. TYERS.

Remembering the statement in the previous chapter that the longer the wave-length the greater is the amount of inductance required to tune it in, it will be obvious that it is impossible to wind up one coil to receive all wave-lengths. The range of the set here described is from about 350 metres to 600 metres.

Construction of the Tuner.—The coil will be wound on a cylinder 6 in. long and 3 in. in diameter. Cardboard postage tubes are very suitable for the purpose if they are previously prepared. A 6-in. length is cut off with a saw and the surface and ends are carefully smoothed with very fine glass-paper. Three small holes are drilled in each end of the tube in the position shown in Fig. 7. The tube is then heated in an oven to drive out any absorbed moisture, and while it is still hot it is given a coat of thick shellac varnish. This is prepared by dissolving shellac in methylated spirit. The tube should be heated and varnished at least three times.

Wooden ends are fixed to the cylinder, which serve as a support for the slider, as follows: Two wooden discs about $\frac{3}{8}$ in. thick are cut out with a fretsaw of such size as tightly to fit into the ends of the tube. This will be understood by reference to Fig. 8, and

it will be seen that they are afterwards secured by small brass screws passed through the sides of the tube. The end pieces are made from any hardwood, and should be about $4\frac{1}{2}$ in. square and $\frac{1}{2}$ in. thick. These are fixed to the discs by brass screws after the coil has been wound.

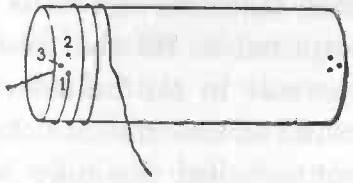

Fig. 7.—Method of Fixing Winding.

Winding the Coil.—When winding a very large coil it is usual to arrange some form of winding apparatus, but it is unnecessary in this case. Referring to Fig. 7, about 6 in. of free end of the wire is passed down hole No. 1, up hole No. 2, and down hole No. 3, the end being put through the loop which has been formed inside the tube between holes No. 1 and No. 2. It will be found that this will fix the end of the wire quite firmly. The winding is then started, making each turn close against the other. It is essential to keep the wire fairly tight, but not so tight as to strain it. When the other end of the coil is reached the wire is fastened off in a similar manner to the first

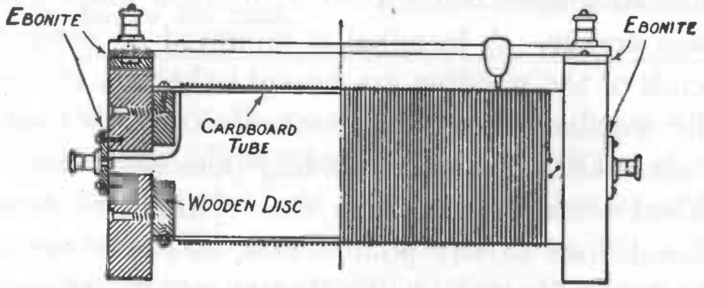

Fig. 8.—Half Section of Tuning Coil.

turn. The best wire is double silk-covered, but this, of course, is rather expensive, and cotton- or enamel-covered may be substituted. It should be remembered that enamelled wire is thinner than silk-covered, and therefore if this is employed more turns will be required to fill the winding space, with a consequent increase in the inductance of the coil. It is not very usual to use silk- or cotton-covered wire with a sliding contact, but this may be done if the winding is given a thin coat of shellac.

Mounting the Coil.—Although a connection is only required to one end of the winding, it is useful to bring both ends to terminals for use in other circuits. A hole about $\frac{3}{4}$ in. in diameter is made in the centre of each wooden disc and end piece. Two squares of ebonite about $1\frac{1}{2}$ in. long are placed over the holes in the end pieces, being fixed with small brass screws at each corner. A terminal is mounted on each, and the ends of the winding are brought through the holes in the wooden disc, being connected to the back of the terminals. Thus the winding does not come into electrical contact with either the cylinder or wooden ends and discs at any point; this, of course, ensures the best possible insulation. Having reached this stage the end pieces can be screwed to the wooden discs, thus firmly fixing the coil.

The Sliding Contact.—The slider may be made if desired, but as it is a standard detail it can be purchased cheaply. It consists of a piece of moulded ebonite containing a spring and brass plunger which makes contact on the winding of the coil. Usually

the slider is made to fit a $\frac{1}{4}$-in.-square brass rod, as shown in the diagram. A piece of square brass rod is cut about 7 in. long (that is, the length of the tube and end pieces), and a hole is drilled in each end to take a small terminal screw. Two pieces of ebonite are next prepared. These should be made about 1 in. long and $\frac{1}{8}$ in. thick. The width is that of the end piece, the ebonite being fixed to this as shown in Fig. 9. It will be noticed that a hole is drilled in the middle of the ebonite, a small part of the end piece being cut away to accommodate the head of the terminal screw. The screw is put through the ebonite, passed through the hole in the square brass, and the two parts of the terminal are screwed up tightly. The same process is repeated at the other end of the square brass, and the pieces of ebonite are then screwed to the ends.

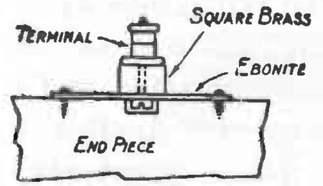

Fig. 9.—Method of Fixing Slider Rod to End Piece.

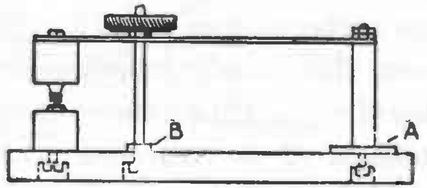

Fig. 10.—Simple Detector.

Two terminals are connected to the slider rod, whereas only one is needed. This makes the appearance of the coil symmetrical, and the additional terminal may sometimes be of use in different circuits.

The Contact Line.—The coil is now complete with the exception of the coil contact line; where the slider touches the winding the insulation must be removed. This is best accomplished by rubbing it with a piece of very fine glass-paper, using the edge of a straight piece of wood as a guide, so that a neat line of bare copper wire appears. Only just sufficient insulation should be removed to ensure the slider making an efficient contact.

The Crystal Detector.—There are a number of different forms of detectors (see Chapter II of the "Amateur Wireless" Handbook "Wireless Component Parts"), the most stable type probably being the carborundum and steel-plate combination. However, this usually requires a potentiometer, and it is therefore a little more complicated. Another type consists of a very fine wire (called a cat-whisker) which bears lightly on the surface of the crystal. This combination is perhaps a little more sensitive than others, but at the same time it is rather erratic in behaviour. The set here described has a perikon detector.

The detector will be understood by reference to Fig. 10. The base may be of ebonite, 4 in. by 3 in. and $\frac{1}{2}$ in. thick. The crystal cups may be drilled or turned from brass rod $\frac{1}{2}$ in. in diameter, or they may be bought for a few pence. The success of the detector depends upon its rigidity; a weak or springy detector will never keep sensitive for more than a few minutes, and it will be found a source of everlasting annoyance. One crystal cup is fixed near the end of the base, as shown in Fig. 10, and the other is screwed to the end of a piece of brass $2\frac{1}{2}$ in. long, $\frac{1}{2}$ in. wide, and a little less than $\frac{1}{16}$ in. thick.

A thick brass screw about 2 in. long is passed through a hole drilled at the other end of the base. A strong washer (A, Fig. 10) is put on the screw, together with a length of stout brass tube about $\frac{3}{8}$ in. external diameter. This is followed by the brass strip, which is finally secured by two nuts. The length of the brass tube will depend, of course, upon the height of the crystal cups. A similar but longer screw is fixed to the base with a nut B, and the end is allowed to project through a slit in the brass arm. A nut to fit the screw is soldered to a small piece of thin brass, which is then screwed to an ebonite knob. It will be understood that by screwing the knob downwards the two cups will be brought nearer together, thus varying the pressure between the crystals. The crystals are set in the cups with either molten solder or Wood's metal. It is usual to employ a pointed piece of bornite or copper pyrites resting on a flat face of a piece of zincite. Two terminals mounted on the base complete the detector; connection is made, of

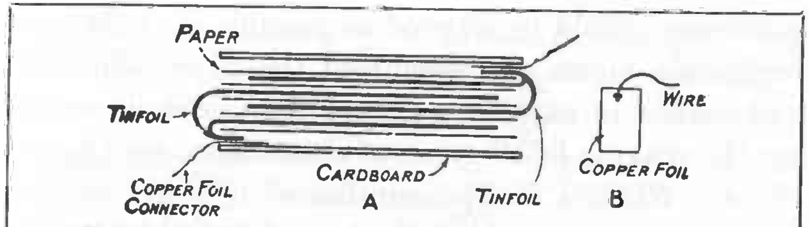

Fig. 11.—Diagram showing Construction of Telephone Condenser.

course, to the fixed cup and the screw holding the upright.

The Telephone Condenser.—This can be made very simply from tinfoil and paper. The actual value of the condenser is not of very great importance, so that the following details need not be adhered to very strictly. Eight pieces of tinfoil 3 in. by $1\frac{1}{2}$ in. and nine pieces of thick writing paper $2\frac{1}{2}$ in. by $2\frac{1}{2}$ in. will be required. Fig. 11 illustrates the method of assembling the condenser, only four plates being shown for clearness. It is essential that the insulation of the condenser should be as good as possible, and therefore before the plates are assembled the paper should be well soaked in paraffin wax. (For full details regarding the making of all types of condensers, see Chapter IV of " Wireless Component Parts.") When the tinfoil plates are assembled, the four plates which project on one side are bent on to the top piece of paper, and the other four are bent on to the bottom piece of paper. The length of the projecting pieces should be a little over half an inch.

Two pieces of waxed cardboard are cut to the same size as the paper to act as a kind of cover. Connection has yet to be made to the plates, and this is best done as follows: Two short lengths of copper wire are soldered to two small pieces of copper foil. These are placed one against each of the bent pieces of tinfoil, being slipped between the top and bottom pieces of paper and the cardboard. This should be quite clear from the diagram. To ensure an efficient contact the condenser is pressed well together, and it is then firmly bound round with some tough brown paper which is secured with a little gum. To serve as a protection against damp, the finished condenser is painted with hot wax, great care being taken to cover the parts where the copper foil emerges from the paper. If desired, the condenser may be placed in a box, when the wires would be brought to two terminals mounted on a piece of ebonite on the top.

Connecting the Apparatus.—Fig. 12 is divided into two parts. One part shows how the apparatus appears when it is connected up, and the other part shows the standard way of indicating the various components. It will be noticed that a switch has been included between the telephones and the detector. It is so arranged that either of two detectors may be used at will. This is a very convenient method of working, as, should one detector suddenly become insensitive in the middle of an important signal, it is only necessary to put the switch in the other position, thereby connecting up the second detector. As soon as the signal

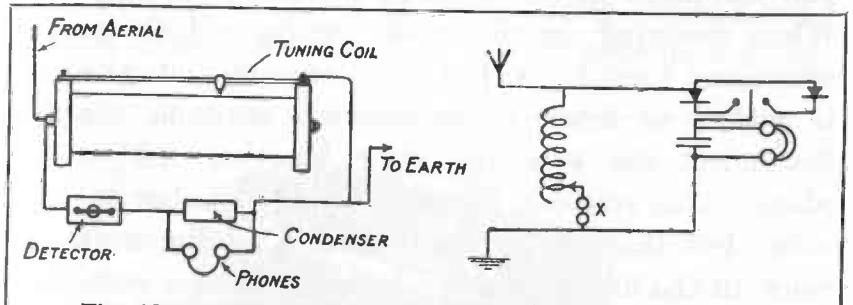

Fig. 12.—Details of Connections showing Arrangement of Apparatus and Wiring Diagram.

has finished, it is possible immediately to readjust the faulty detector. The switch is also very useful for comparing two different types of detectors, since it is possible to change from one to the other without disconnecting any of the apparatus.

Using Loading Coils.—The tuning coil, as previously stated, is designed to receive wave-lengths up to about 600 metres. However, if it is desired to receive longer waves, all that is necessary is to insert two terminals in the position marked x in Fig. 12. When receiving on the small tuning coil these are connected together with a piece of wire, but when it is wished to listen to longer-wave stations, simply disconnect the wire and insert another coil in its place. This coil can be made exactly similar to the other, but there is no need to fix a sliding contact, since all the fine tuning can be accomplished with the original coil. It is only necessary to tap the coil at varying intervals, bringing the tappings to a multipoint switch.

A coil of this description is usually called a loading coil, since it loads the aerial to the required wave-length.

CHAPTER III

Set With Semicircular Tuner

By O. J. RANKIN.

THE tuning inductance of the set described in this chapter (see Fig. 13) has been specially designed for the efficient reception of broadcasting, "dead-end" effects being obliterated as far as possible by only winding on enough wire to just cover the broadcasting wave-lengths.

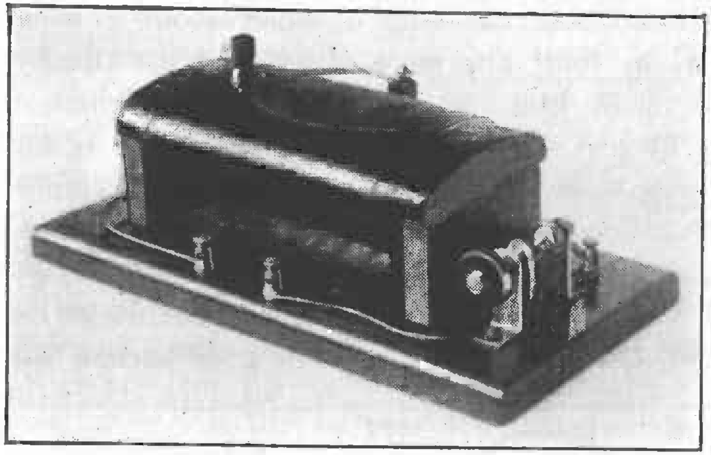

Fig. 13.—Photograph of Set with Semicircular Tuner.

Materials.—The materials and parts required to build this receiver comprise one cardboard cylinder or "former," 6 in. long by 4 in. diameter, ½ lb. bobbin of No. 24 (or nearest) enamelled copper wire, one baseboard $\frac{1}{2}$ in. thick, 14 in. long and 8 in. wide, one piece of board $\frac{3}{4}$ in. thick, $3\frac{7}{8}$ in. wide and $7\frac{1}{2}$ in. long, two pieces of board each about $\frac{1}{2}$ in. thick, $3\frac{7}{8}$ in. wide and 3 in. long, one strip of wood about $\frac{1}{2}$ in. square by $3\frac{1}{2}$ in. long, one piece of spring brass (hard-rolled brass) 4 in. long by $\frac{3}{8}$ in. wide, also one piece $1\frac{1}{2}$ in. long by $\frac{1}{2}$ in. wide, two strips of $\frac{1}{8}$-in. brass $1\frac{3}{4}$ in. long by $\frac{1}{2}$ in. wide, one crystal cup and crystal (preferably hertzite or permanite), one small terminal with nut, four medium-size wood-screw terminals, length of 2 B.A. screwed rod and six nuts, two ebonite or wooden knobs, one spring washer, some good shellac varnish, about one yard of connecting wire and systoflex, and a quantity of small nails, screws, and washers and other sundries.

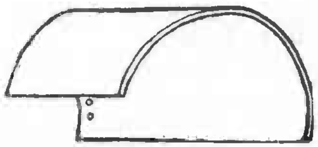

Fig. 14.—Former for Coil.

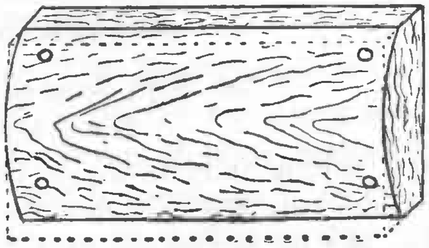

Fig. 15.—Wooden Support for Former.

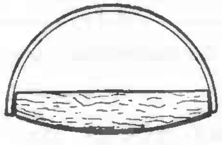

Fig. 16.—End View of Former.

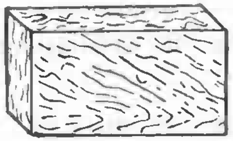

Fig. 17.—End Support.

Inductance Coil.—Cut the cardboard cylinder lengthwise, as shown by Fig. 14, and put aside the other half, as this will not be required. Take the thick piece of board, $3\frac{7}{8}$ in. wide by $7\frac{1}{2}$ in. long, and shape it as shown in Fig. 15. Fit this to the inside of the semi-cylinder, as shown in Fig. 16, and secure it with a few small brass nails driven in so that the heads are flush with the cardboard. See that the straight edges of the cardboard are flush with the curved edge of board, and that an equal portion of board is left projecting at each end. Give this a coat of shellac varnish inside and out, and when perfectly dry apply a second coat. When this is quite dry screw on the two end supports (Fig. 17), which are the two pieces of board $3\frac{7}{8}$ in. wide by 3 in. long, as shown in Figs. 18 and 19. Attach the end of the wire from the bobbin to a small screw T (Fig. 19), apply another coat of shellac, and while this is still "tacky," wind on the wire, taking care that there are no spaces between the layers, particularly where it covers the top curved portion. Having finished it, leave about six or eight inches of wire at the end, and pass it through the holes shown in the cardboard in Fig. 14 to prevent it

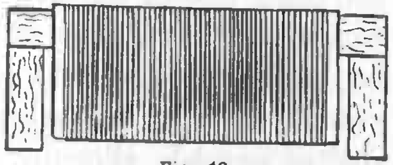

Fig. 18

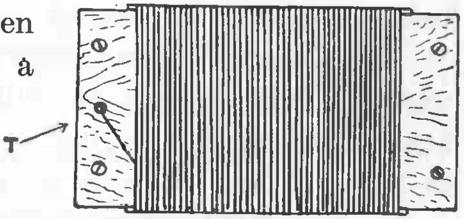

Fig. 19

Figs. 18 and 19.—Elevation and Plan of Coil.

unwinding. Apply shellac freely over the winding and allow the coil to dry.

Next take the piece of spring brass 4 in. long by $\frac{3}{8}$ in. wide, round off the corners with a smooth file, and drill a hole in each end (see Figs. 20 and 21), one of which must take a length of the 2 B.A. rod and the other a round-headed wood-screw. Cut off about 1 in. of the screwed B.A. rod and fit one end into a suitable wood or ebonite knob, as shown in Fig. 22. Bend the other end of the strip slightly, so that it is parallel to the projecting part of the rod. The latter should be made quite smooth and rounded off to a blunt point. Give the baseboard at least three coats of shellac varnish, allowing each coat to dry thoroughly before applying the next.

The Detector.—The construction of the crystal detector should present no difficulties. The two $\frac{1}{8}$-in. brass strips should be cut out and drilled as shown in Figs. 23 and 24, and bent at right angles at the dotted lines. The shank of the terminal fitted to one crystal cup (Fig. 25) should slide freely in the slot (Fig. 24). This small terminal should, of course, be fitted before mounting the crystal.

Take the piece of spring brass $1\frac{1}{2}$ in. long by $\frac{1}{2}$ in. wide as shown by Fig. 26, solder the fine wire feeler or "cat's whisker" U (Fig. 27) to one end and bend to the shape shown. Solder the other end to the base of the piece of brass (Fig. 23). The hole at the top of the pillar should be tapped 2 B.A. An alternative method is to drill the hole slightly larger than the diameter of the detector screw and solder on a nut

previously filled with clay to prevent the solder adhering to the thread. The detector screw (Fig. 28) is self-explanatory. A suitable wood or ebonite knob is clamped tightly to a short length of the 2 B.A. rod with two nuts, as shown, and the end of the rod rounded off to a point. The general arrangement of the detector is clearly shown in Fig. 29.

Fig. 20

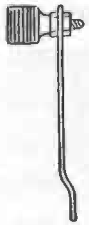

Fig. 21

Fig. 22

Fig. 24

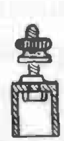

Fig. 25

Fig. 26

Figs. 23 to 28.—Details of Detector.

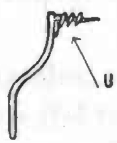

Fig. 27

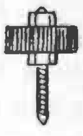

Fig. 28

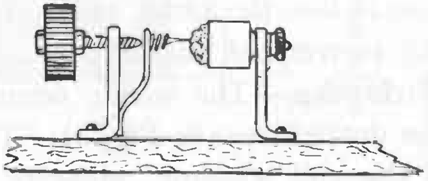

Fig. 29. Detector Assembled.

Assembling.—Place the mounted coil on the centre of the baseboard, move it along to the left about $1\frac{1}{2}$ in., see that everything is quite square, and with a pencil mark all round the bases of supports. Drill four holes large enough to take the screws, and screw the two parts firmly together as shown in Fig. 30. Take the strip of $\frac{1}{2}$-in.-square wood, place it at the back and on a line with the centre of coil, and attach it to the base in a similar way. The correct position of this, which is the support for the inductance switch arm, is shown in Figs. 30 and 31. Now screw down the switch-arm with a medium-size round-headed wood screw and the spring washer. The point must make good contact with every turn of wire on the coil, and to get it perfect it may be found necessary to bend the arm slightly one way or the other. Rotate the arm across the coil several times so as to make a distinct mark across it, as shown in Fig. 31, then with a piece of emery-paper wrapped round any pointed instrument carefully remove the enamel along that line, leaving the bare copper to make contact with the point on the switch arm. Screw the detector to the base and place the aerial, earth and telephone terminals in any convenient position.

Wiring-up.—The wiring connections are indicated by the dotted lines in Fig. 31. Take the end left over from the coil winding, measure the distance to the aerial terminal marked A, remove the enamel, clean thoroughly with emery-paper, and wind it once round the shank of the terminal. Insulating sleeving should be slipped over all connecting wires. Connect another short length of wire from the aerial terminal to the detector pillar which holds the crystal cup, placing the end under one of the screws or soldering it direct to any convenient part of the pillar. This latter

method is always preferable. From the detector pillar carrying the detector screw connect a wire to the nearest phone terminal, from the other phone terminal to the earth terminal marked E, and from E to the

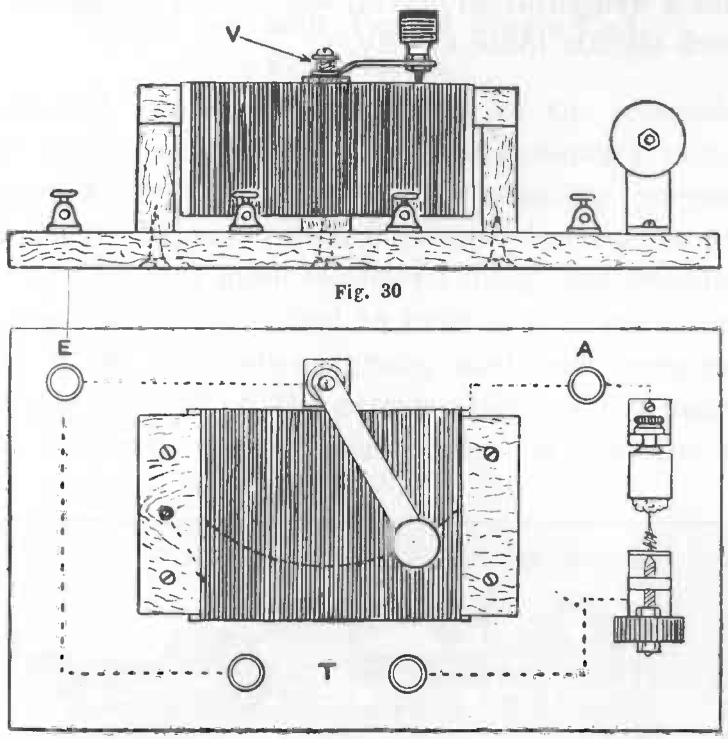

Fig. 30

Fig. 31

Figs. 30 and 31.—Elevation and Plan of Complete Receiver.

spring washer V (Fig. 30), which, of course, should be soldered. It may be necessary to add that the other end of the coil winding terminates at E.

It will be easily understood that the point on the switch arm represents the end of the winding in the sense that only the turns of wire between the connected end of the coil and the switch-arm contact are actually being used. By rotating the switch-arm the inductance is made variable.

This receiver is extremely simple to operate, and with a well-adjusted crystal will receive telephony and spark signals quite clearly.

CHAPTER IV

Crystal Set with Tapped Single Coil

By A. J. COOPER.

Single-coil Tuner.—A photograph of the completed tuner is shown by Fig. 32. The secondary circuit detailed later is not essential for receiving purposes and can be dispensed with if desired, but its use permits of finer and more selective tuning, and therefore the constructor is advised to include it in his instrument. The bar-switch, studs, and two terminals shown in Fig. 32 on the extreme right of the instrument illustrate that portion of the arrangement re-

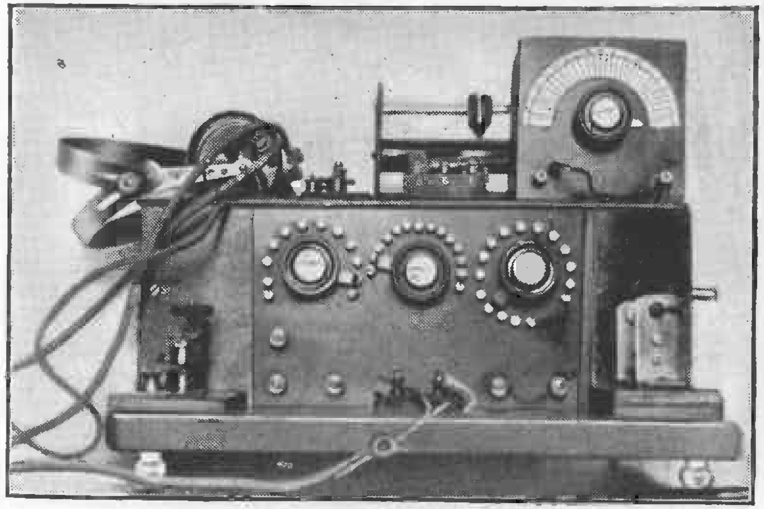

Fig. 32.—Photograph of Complete Tuner.

lating to this secondary circuit, and will be dealt with later on.

Should the constructor decide to embody the secondary circuit in his set he should prepare the panel for its reception according to the sketches, etc., as to do so later will necessitate dismantling the set.

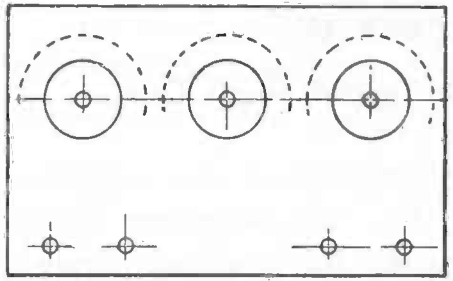

Fig. 33.—Lay-out of Ebonite Panel.

The material detailed does not include the material for the closed circuit, which necessitates an additional 12 studs, 2 terminals and bar-switch.

Panel.—The panel which carries the tuning switches

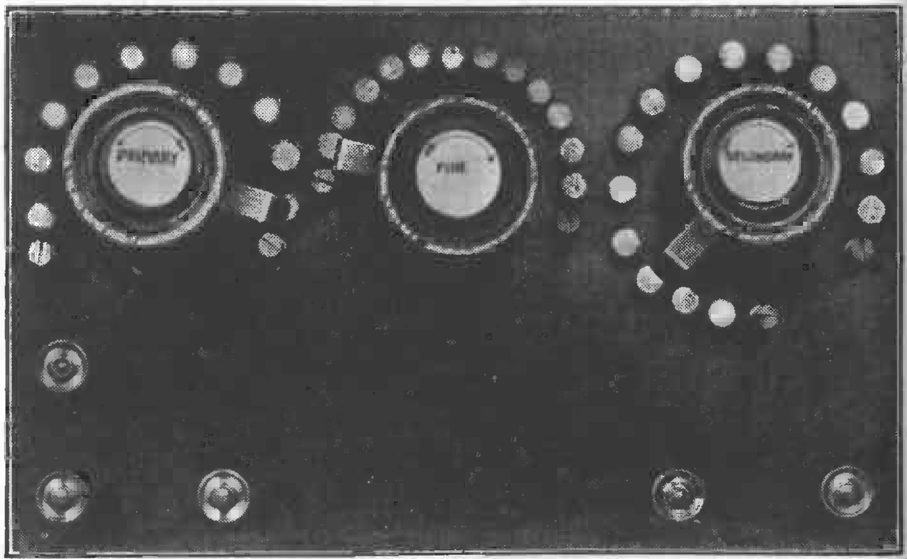

Fig. 34.—Photograph of Panel and Tuning Switches.

will first be dealt with, and a sketch showing the lay-out is given in Fig. 33.

First take the ebonite and smooth off the rough edges to the dimensions specified, that is, 8¾ in. by 5¼ in. Prepare a sheet of paper marked with the required dimensions and glue it to the ebonite. The holes required for two sets of 10 contact studs, etc., can now be drilled. The sizes of the holes and distances apart are not given, as these must be bored to the dimensions of the material obtained. The positions of the contact studs will vary according to the area of their bearing surface, but they should be placed so that the bar-switch cannot fall between them. When boring tapping holes for screw-threads a drill must be put through of the dimension of the inside of the thread for which the hole is intended. Care must be taken when working on ebonite not to exert too much pressure, as the material is very easily broken

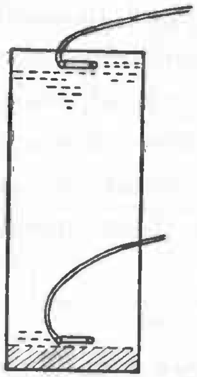

Fig. 35.—Method of Securing Wire.

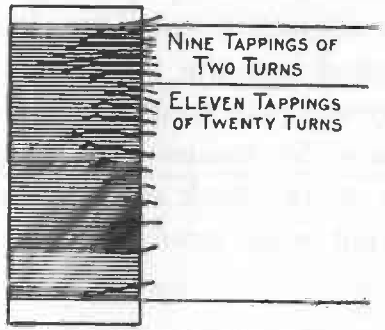

Fig. 36.—Details of Tappings.

and also the ebonite might be torn away on the under side, leaving an ugly, uneven edge. When all the holes are drilled, those which are intended for screw-threads should be tapped according to the size for which they are intended.

A photograph of the completed panel is shown in Fig. 34, and this incorporates the bar-switch and studs and terminals for the secondary coil. After the insertion of the contact studs and terminals (the threads of which should previously be dipped in shellac) in their respective positions, the bar-switches should be mounted and the tip of the switches adjusted so as to give equal contact on the centre of each stud. Ensure, by means of pinning or soldering, that the nuts on the back of the panel on these bar-switches will not work loose.

Materials for Instrument and Aerial

¼ lb. No. 28 s.w.g. d.c.c. wire.

A cardboard cylindrical former 3½ in. in diameter and 5 in. long. (Should a former of these dimensions not be procurable a Horlick's Malted Milk dummy will meet requirements.)

2 bar-switches with two nuts and spring washer.

Small quantity of shellac varnish.

Crystal cups, crystals, and sundry brass-strip and screws.

2 terminals with large bearing surfaces between the nuts.

2 binding-post terminals (for telephones).

1 pair of high-resistance phones (total resistance of 4,000 ohms).

1 fixed telephone condenser .003 microfarads.

1 sheet of ebonite 8¾ in. by 5¼ in.

20 contact studs.

Wood for case, quantity specified in diagram, Fig. 37, ⅝ in. thick (this wood should be very well seasoned).

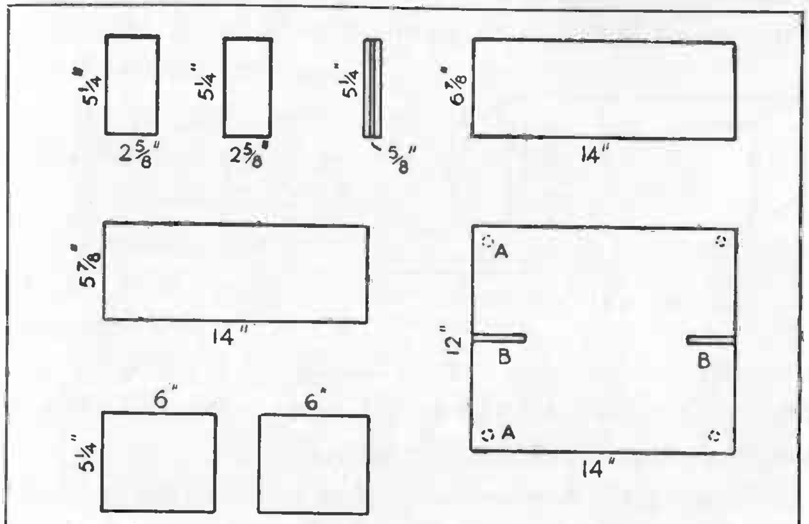

Fig. 37.—Details of Material for Case.

4 small china insulators (feet for instrument).

100 ft. of 7/22 bare or insulated copper wire.

8 2-in. china " reel " insulators with ½-in. diameter hole in centre.

A pole or poles not shorter than 22 ft. if possible.

Tuning Coil.—Should the coil former be of cardboard it should be put into a moderately hot oven for five minutes and then shellac-varnished. If the former is of ebonite, paxolin or any other specially-prepared material, this process need not be resorted to.

Shellac varnish may be made by dissolving about 4 oz. of shellac in half a pint of methylated spirit.

Now take the former and cut out a disc of wood $\frac{5}{8}$ in. in thickness to fit exactly in one end and glue it in position. Two holes of about $\frac{1}{16}$ in. should be made about $\frac{1}{2}$ in. apart on this end of the former and the end of the No. 28-gauge wire inserted and made fast in these holes, being wrapped round as shown in the sketch Fig. 35, leaving a free end protruding from one hole about 12 in. long. Proceed to wrap the wire round the former, taking off tappings every twenty turns for the first 200 turns, and then every two turns for another 18 turns.

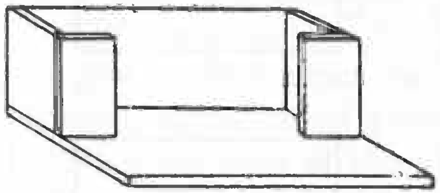

Fig. 38.—Case Assembled.

Tapping the Coil.—The method of making the tapping is to take the wire and turn a length of about 12 in. back on itself, twisting it two or three times between the finger and thumb and leaving a loop of 6 in. When the winding of the coil is completed, thoroughly clean the cotton covering from the wire where it is twisted, apply some powdered resin and solder it. When the soldering is completed, one side of the wire loop can be cut, and this will result in a lead of about 12 in. long being left, which is subsequently soldered to the contact stud.

An alternative method of making the tapping leads is to leave the wire twisted and to bare the end of the loop and solder this to the contact stud, but this method is not so neat or efficient. A loop of 9 in. should be taken if this method is used in order to allow sufficient wire to reach the contact stud.

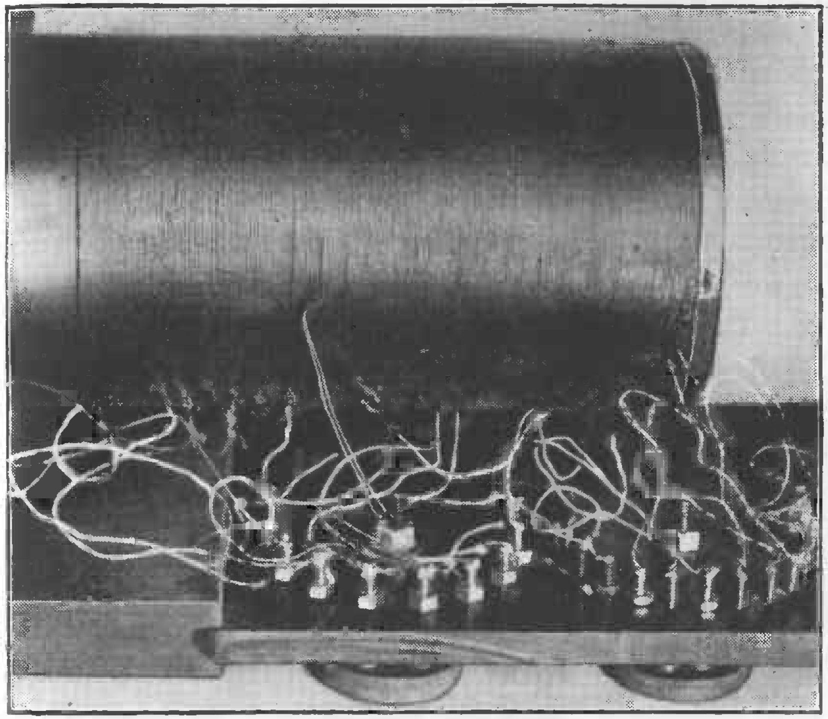

Fig. 39.—Photograph of Coil Connected to Panel.

Finish off the winding in the same manner as it was commenced, leaving a free end of 1 ft. On completion of the winding and the soldering the coil should be given two or three good coats of shellac. The tappings are illustrated in Fig. 36.

Case.—The next operation is to prepare the case for the reception of the coil and the panel. This should be of $\frac{5}{8}$-in. hardwood. Mahogany, teak or oak is to be preferred, but ordinary white wood or pine can be used if it is well seasoned. The case may be french-polished or stained and varnished, according to taste. Prepare the case according to the dimensions and lay-out given in Fig. 37, and use only screws in its construction. The right-hand side and top and bottom should be easily removable, otherwise the constructor can carry out the work according to his skill in joinery, providing the dimensions given are adhered to. The case when finished should appear as in Fig. 38.

A photograph of the coil with wires soldered is given by Fig. 39.

In order to attach the wires of the coil to the panel, as shown in the photograph (Fig. 39), lay the panel on the bench with the bar-switches assembled in position and its top towards the constructor, and place the coil with the end with the wooden end piece to the left and solder the free end to the first contact stud and the loops in rotation to the remaining studs. Keep the leads as short as possible consistent with leaving room to fix the coil and panel in the case and for other wiring. The tappings of twenty turns should now be on the left-hand switch and the two-turn tappings on the right-hand switch, the second free end being soldered to the last right-hand contact stud when completed.

It will now be seen that when the bar-switches are in a position where they point to each other the

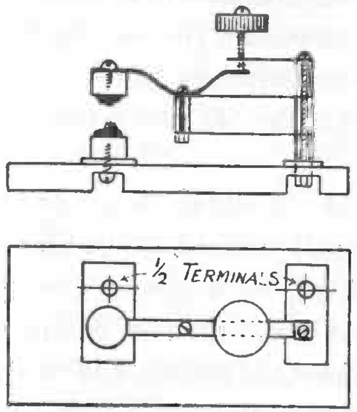

Fig. 40.—Elevation and Plan of Detector.

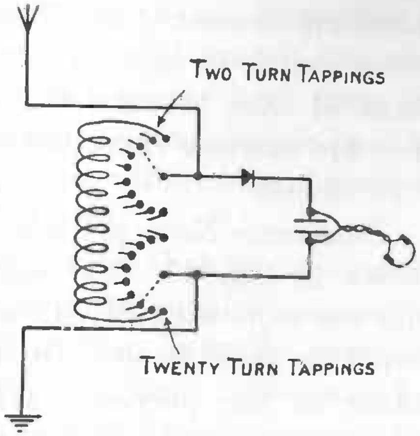

Fig. 42.—Circuit Diagram of Receiver.

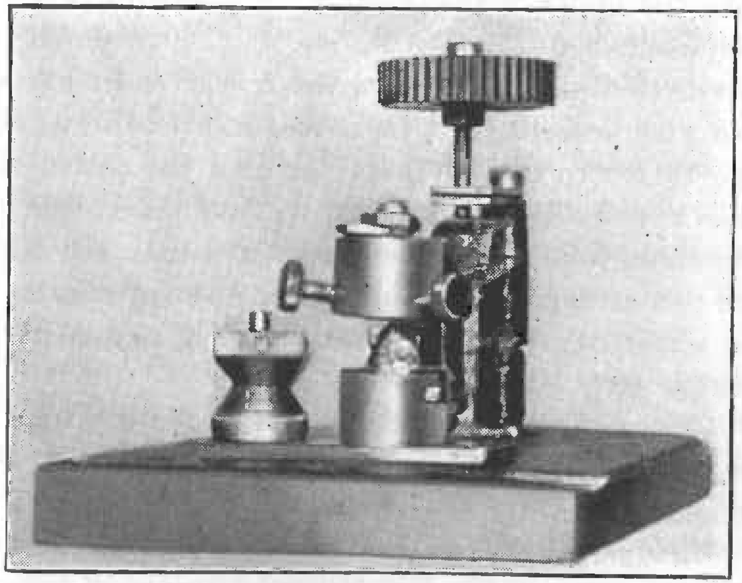

Fig. 41.—Photograph of Detector.

minimum amount of coil is in circuit, and that rotating either switch to right or left increases the number of turns of wire between the bar-switches until, when they are extreme right and left, the whole of the coil is in circuit.

Detector.—Now prepare the crystal detector as shown in Fig. 40. The crystals should be soldered into the cups with Wood's metal, with the screws inserted in their bases. On no account use ordinary solder for this purpose. When the screws are withdrawn they will leave a path for their re-entry into the cups when affixing them in position on the detector. Zincite and copper-pyrites or zincite and bornite are recommended, the zincite in each case being the upper of the crystals. A photograph of the completed detector, which should be mounted on ebonite or dry, well-seasoned wood, is given by Fig. 41. Two such detectors can be made, and it is an advantage to incorporate both of them in the instrument with a suitable two-way switch, as one might be sometimes found to be more sensitive than the other, and this arrangement also facilitates the comparing of the sensitivity of one crystal or set of crystals with another set.

The constructor may now complete the wiring of the panel with 18 S.W.G. tinned copper wire (see Fig. 42).

Wiring.—Particular care should be taken that all connections are made fast either by means of nuts or soldering. When applying the soldering-iron to terminals or studs in the panel do not apply it too hot,

as this is likely to spoil the insulating properties of the panel. A wet rag may be held against the stud being soldered, and this will take the heat from the panel. Ordinary 1/18 rubber-covered electric lighting cable can be used for the wiring with the braid stripped off (not the rubber), or bell wire.

It will be noted by the reader that the number of contact studs on the front of the panel illustrated in the photograph differs from that actually provided for, and also there is an extra terminal. The reason for this is that the writer has used the instrument for certain experimental purposes, such experiments necessitating an additional number of studs, etc., being used, but there is no need for the present construction to embody them.

Assembling.—The crystal detector and phones might be mounted in the position shown in the photograph (Fig. 32), and this has been found to be very convenient, the wiring being under the base and the instrument being kept insulated by the small china insulators. The constructor can, however, use his own discretion as to the position of these accessories. Two detectors are shown in the photograph, one being the perikon and the other a " cat's whisker." A potentiometer, carborundum detector and condenser are also shown on the top of the instrument ; these will be described in the next chapter. The wire between the back of the aerial and earth terminals and the bar-switches should be electric-bell flexible wire, as this will allow for rotation of the switch.

Fix the coil by screwing it to the inside of the left-hand side of the case in a convenient position about midway across the side and about ½ in. from the base of the instrument.

Testing the Set.—To operate the present instrument the crystal detector should be adjusted, and the contact between the two crystals should be light. A buzzer might be sounded near the coil or earth lead, and when the note of this buzzer is heard in the telephones the crystal is in a sensitive condition. Rotate the left-hand switch until signals are heard, and finish by fine tuning on the right-hand switch.

CHAPTER V

A Loose-coupled Set

By A. J. COOPER.

THE apparatus described in this chapter is of a more advanced type than that described in the previous chapter, and includes a tuner with a secondary closed circuit. The general constructional details, however, excluding the loose-coupler, are the same as in the set described in that chapter.

Materials.—The materials required are as follows: A cylindrical former 4½ in. long by 2¾ in. in diameter, 1 oz. 36 d.c.c. wire, a length of ⅜-in. dowelling, 12 contact studs, 1 bar-switch, 2 terminals, 15 ft. of electric-bell flexible wire.

The Former.—First take the former and prepare two wood or ebonite end pieces exactly to fit in the end, with a hole ⅜ in. in diameter bored through the centre of both, as illustrated at A in Fig. 43. If wood is used it should be perfectly dry and of a thickness of about ½ in. Should ebonite be used, it need be only ⅜ in. thick. In one of the end pieces drill ten or twelve small holes, as illustrated at B, Fig. 43.

The former, if of cardboard material, should be prepared with shellac varnish as specified for the primary former. Now draw a straight line down one side, mark off ½ in. from each end, and beginning just inside these marks bore twelve holes right through the former at equal distances from each other. The positions of these holes should be marked on the former before the commencement of operations. A second hole should now be drilled near the first and last holes for making the end of the wire fast. A diagram of the former prepared to these instructions is given by Fig. 44.

Winding the Former.—Now take the 36-gauge wire and commence winding it on to the former in precisely the same manner as adopted for the primary coil, with the exception that the end of the wire has first of all a length of the flexible electric-bell wire soldered to it and is then pushed through the hole into the former. A slip of paper numbered 1 should now be attached to this flexible lead, which should be about a foot long. Proceed with the winding, and meeting the first hole strip the cotton covering off the twisted wire and solder a flexible lead to this; insert it through the hole and number it 2. Proceed with the winding, and ensure that the next turn of wire bears closely against the one just soldered, and so carry on the soldering and numbering of the leads as the holes are reached until the coil is completed, when twelve flexible leads should be obtained from the end of the former farthest from the starting end. The leads will be numbered 1 to 12. Now insert the end pieces into the former, securing them in position by small brass screws, the one with the small holes being utilised at the end of the coil from which the leads emerge, the leads being passed through the small holes. The numbered tickets should be taken off the leads one at a time whilst they are being pushed through, and then re-attached after the lead is through.

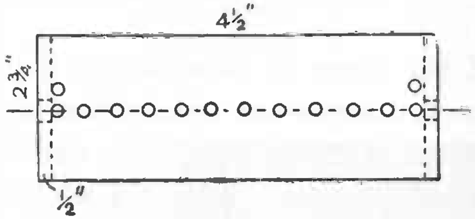

Fig. 44.—Diagram of Former.

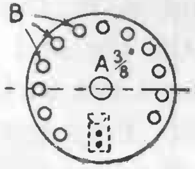

Fig. 43.—End Piece.

The primary-coil end piece should now have a hole bored through it ⅜ in. in diameter, and it is preferable that this should be done with the end piece detached from the coil.

The Sliding Arrangement.—Next take the dowelling and cut off a length exactly to fit inside and across the length of the case—that is, 12½ in. long if the case has been made to the specification—and prepare another piece 8 in. long.

Prepare a small brass right-angle bracket 1 in. each way from the apex of the angle, and bore two holes

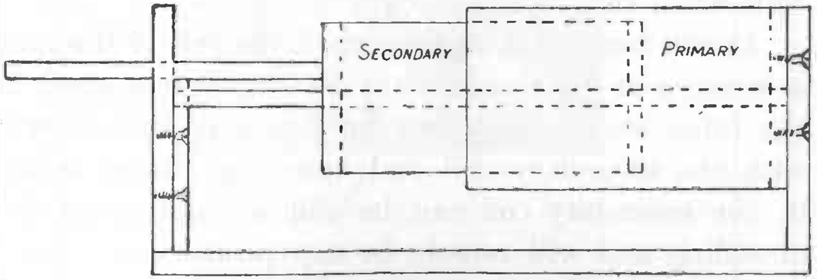

Fig. 45.—Diagram of Loose-coupler.

in each side to take small wood screws $\frac{1}{4}$ in. long and about $\frac{1}{16}$ in. thick.

On the end of the piece of dowelling 8 in. long make a flat surface and screw one side of the bracket to it. Prepare a piece of wood $\frac{1}{2}$ in. thick and $2\frac{3}{4}$ in. by $2\frac{3}{4}$ in. and take off the end of the case which does not hold the primary coil. This side would be the right-hand side when the case is facing the constructor. Now pass the piece of dowelling which is to fit exactly into the case through the secondary coil, and see that it slides easily and freely; then place the end in the hole just made in the end piece of the primary. Position the coils and dowelling in the case against the left-hand side about 1 in. clear of the base, and place the piece of wood $2\frac{3}{4}$ in. by $2\frac{3}{4}$ in. against the other end of the dowelling and resting on the base of the case. Adjust the coils and dowelling to a horizontal position, and mark on the piece of wood the centre position of the dowelling and bore a hole $\frac{3}{8}$ in. in diameter at this position. Now screw the wood to the end piece of the case which has been removed, seeing that it is in a line with the centre line of the coils when they are positioned in the case.

It will now be clear that when the end of the case is screwed in position and the primary coil secured to the other end of the case by means of two screws, with the secondary coil and dowelling placed inside it, the secondary coil can be slid up and down the dowelling and will remain in any position.

Now take the piece of dowelling with the right-angle bracket attached to it and secure the other side

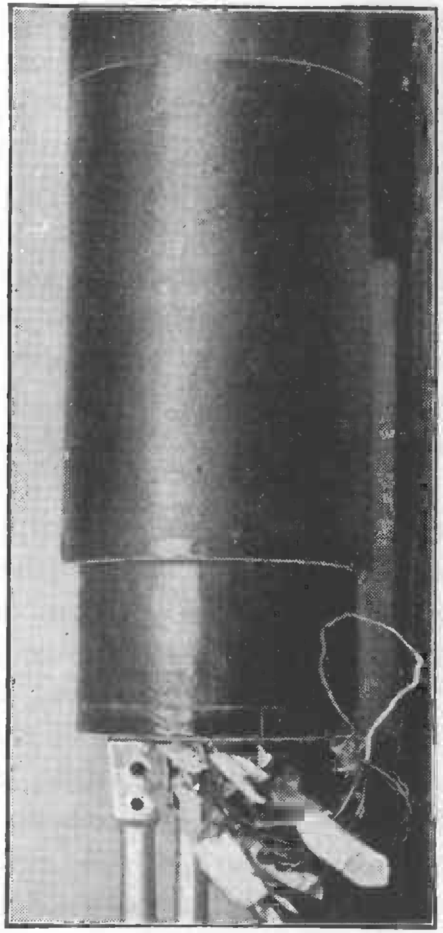

Fig. 46.—Photograph of Loose-coupler.

of the right-angle bracket to the secondary-coil end piece through which the flexible leads emerge. A hole must now be bored through the end of the case which has been removed to allow this piece of dowelling to project, and this forms the rod by which the coupling of the coils is varied. The coil when viewed from the back will now appear as in Figs. 45 and 46.

Solder the ends of the flexible leads and the contact studs of the secondary bar-switch, fix the coils in position in the case, and wire up the remainder of the circuit, as in the diagram (Fig. 47). From this diagram it will be seen that the secondary coil, crystal detector, phones and variable condenser are in an entirely self-contained or closed circuit, and the primary coil is in a separate circuit in a position between aerial, and earth.

The Closed Circuit.—There is no apparent connection between the two circuits, but the connection is made by induction between the two coils. To put it simply, the oscillating current passing through the primary coil on its way to earth sets up magnetic lines of force about the primary, and the secondary coil being close enough to intersect these lines of force, a corresponding current is induced in this closed secondary circuit. These high- or radio-frequency oscillations are rectified or filtered out by the crystal " detector," which allows a high percentage of low-frequency current (sometimes termed audio-frequency) to pass and produce an audible note in the telephones.

The Variable Condenser.—Although not essential, it is customary to employ a variable condenser in

conjunction with the close or secondary circuit, as by its means very fine tuning is possible.

Such a condenser can take several forms for practical work (see the companion handbook " Wireless Component Parts," which also explains capacity calculations), the cheapest and possibly easiest to construct being of the sliding type and made from old photographic negatives and sheet zinc. The glass (with the film cleaned off) is interposed and supported between sheets of zinc of a slightly smaller area, and the movable or sliding sheets of zinc are pushed in between the glass sheets and the fixed zinc plates above and below. In this case the glass is the dielectric.

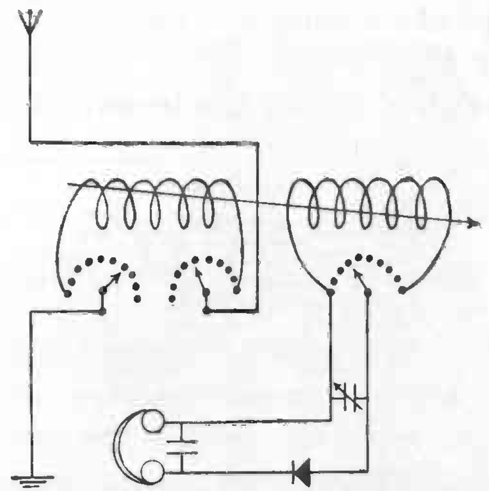

Fig. 47.—Circuit Diagram for Loose-coupled Crystal Set.

A diagram showing the construction of a variable condenser of this nature is given in Fig. 48.

The capacity of a condenser is measured in microfarads, and the size of condenser suitable for the present purpose is .0003 microfarads.

Other forms of condenser are in existence, such as the tubular and rotary-vane type. It is this latter type which is considered by the majority of experimenters as being the most suitable for wireless work generally, as it is compact and smooth in operation. A photograph of a condenser of the capacity prescribed is shown by Fig. 49.

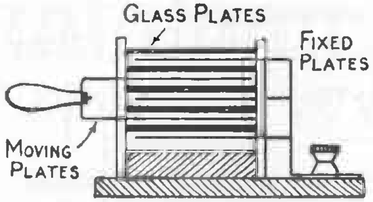

Fig. 48.—Sliding-type Condenser.

Mounting the Variable Condenser.—When assembling the variable condenser, which should have an ebonite panel and base, one of the fixed plates should be placed on the ebonite panel and used as a template for marking off the position of the ties which hold these fixed plates in position. A rotary plate should be placed so that its straight edge is square with the straight edge of the fixed plate but not quite touching it, and the small projecting piece should just fit into the recess cut into the fixed plate for its reception. When the centre of the square hole in the rotating plate has been marked on the ebonite all the holes may be bored with drills of an appropriate size. The

fixed-vane tie rods should be screwed into the ebonite, and for this purpose a tap will be required in order to put a thread in the hole in the panel. The rotary-vane spindle must of course be a close fit to the shoulder on the spindle. When the top panel has been prepared it can be used as a template for the base in which corresponding holes will be required.

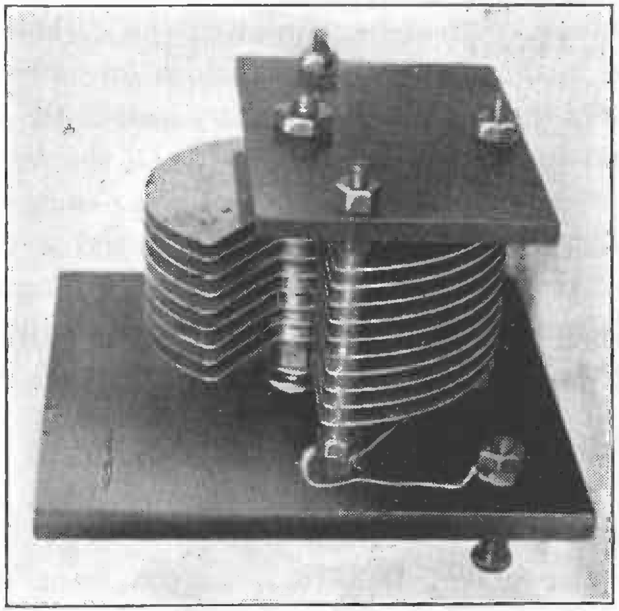

Fig. 49.—Photograph of ·0003 mfd. Variable Condenser.

Additional Experimental Instruments.—It is probably known to many readers that a carborundum detector requires a potentiometer and battery for use in conjunction with it, and that these are required in order to create a difference in potential between the carborundum crystal and steel plate. The reader may like to construct a simple type of carborundum detector, and for this reason dimensions and details are given in Figs. 50 and 51.

Making the Potentiometer.—The potentiometer consists of a piece of wood (broom handle will do) 1 in. in diameter by 4 in. long, wound for 3⅛ in. of its length with No. 36 d.s.c. Eureka resistance wire and mounted between suitable supports. A slider makes contact on the top surface and runs on a piece of brass rod ¼ in. square. When incorporating the carborundum detector in the circuit the wire which formerly led to one side of the perikon detector is joined to the square brass rod by means of a terminal, and the two ends of the resistance wire are connected to each side of a 4-volt dry battery. There is also looped or twisted with one of these battery wires a wire leading to the steel plate on the crystal detector, and another wire runs from the crystal to the telephones. A switch should be incorporated in the potentiometer to cut off the battery current when not in use. The buzzer is used as explained in the previous chapter, and is obtainable for a very small sum.

The Catwhisker Detector.—In the front of the instrument should be placed a simple catwhisker detector, as used in conjunction with certain crystals —for example, galena, rectarite, hertzite, etc. This is simple to construct, and Fig. 52 shows the general arrangement. A photograph is shown by Fig. 53.

The bracket is a piece of brass 3 in. by ¾ in. bent to an angle of 90 degrees. A hole is drilled ½ in. from the top of the long side (2 in. long) to take the screw

which secures the crystal cup. A hole is drilled on the other side (1 in. long) to take a terminal.

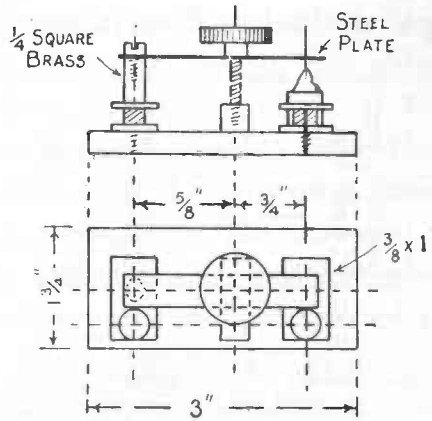

Fig. 50.—Details of Carborundum Detector.

The other bracket is a similar piece of brass bent in the same manner and to exactly the same dimensions.

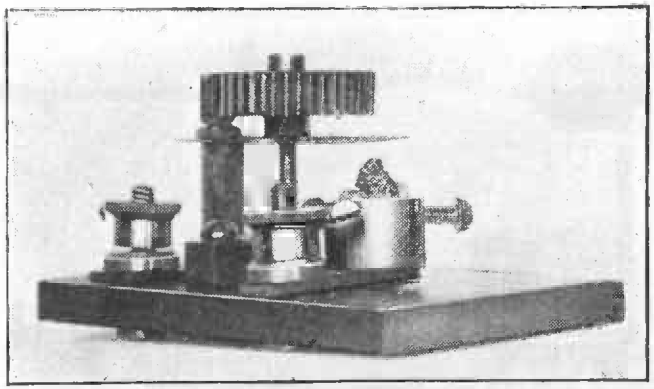

Fig. 51.—Photograph of Carborundum Detector.

A hole is drilled ½ in. from the top of the 2-in. piece, but of a larger diameter—in fact, almost large enough to allow a brass ball to pass through it, but not quite. This brass ball might be ½ in. in diameter, but not larger; the one used on the instrument in the photograph was taken from the top of an old bed rail. A piece of springy brass is prepared 2 in. by ¾ in., and has a similar hole drilled in it. The bracket and the spring are then placed together and a hole drilled through the component parts about ½ in. from the foot of the bracket to take a clamping screw, which should be provided with a nut. The brass ball has a hole drilled right through it to take a piece of stout brass wire 3½ in. long, which is then soldered in place, allowing one end on one side of the brass ball to be 1½ in. long.

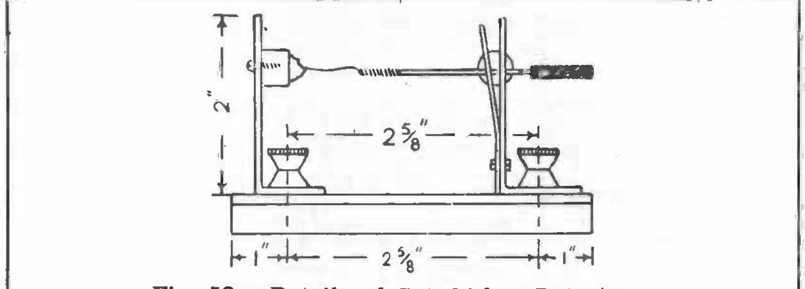

Fig. 52.—Details of Catwhisker Detector

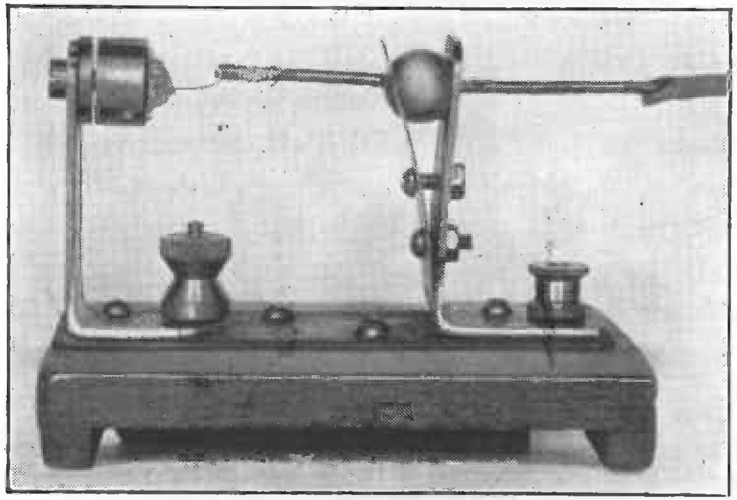

Fig. 53.—Photograph of Catwhisker Detector.

Place the ball in position over the hole in the bracket and fit over it the spring brass, and clamp in position by means of the nut and screw shown. Solder to the long side of the stout brass wire a spiral of wire 36 S.W.G., and on the other end fit a piece of ebonite rod or rubber to act as an insulator when adjusting the position of the fine wire on the crystal. Fit the crystal cup with a piece of crystal and mount the whole on a suitable base of ebonite or hard. dry wood.

CHAPTER VI

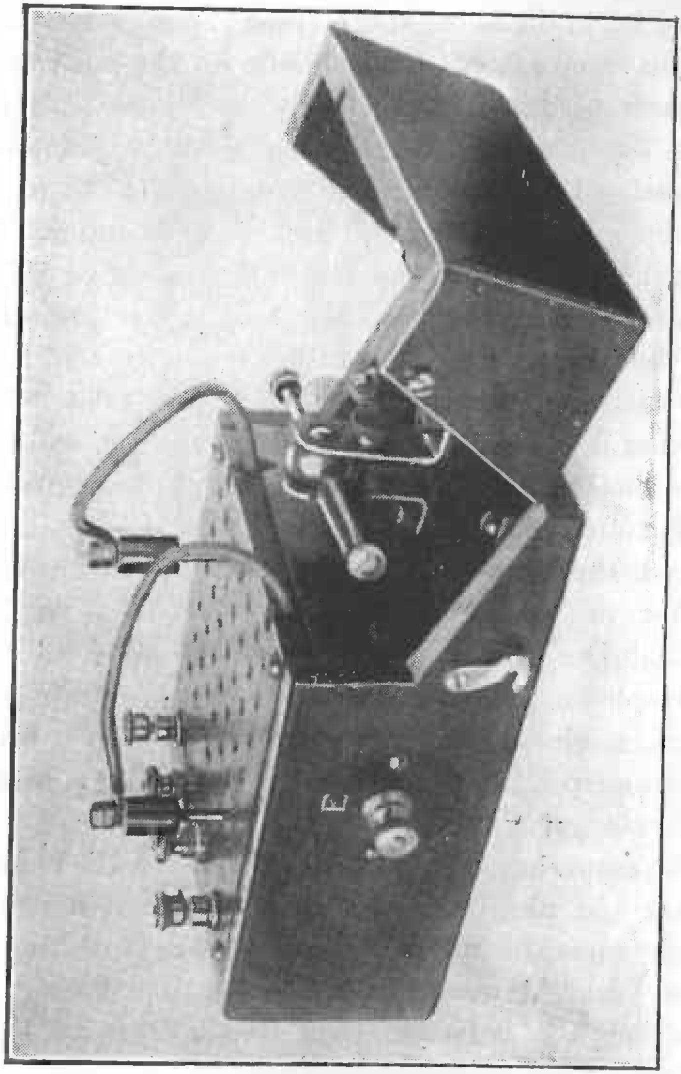
Set with Plug-in Basket Coils

By H. J. TURPIN.

An unusual type of crystal receiver is described in this chapter, one in which is embodied extreme selectivity. Instead of the orthodox slider and cylindrical inductance coil or the variometer methods, the writer has adopted a system of combined adjustment of the aerial and earth connections, each of which can be independently connected to any particular part of an inductance coil of the " basket " type. It is claimed that by this method (which is explained more fully later) an amount of wire equal to $\frac{1}{2}$ in. can be added to or subtracted from the total quantity in the inductance circuit depending upon the relative position of the aerial and earth tuning plugs. The set is shown photographically in Figs. 53A and B.

In order to ensure that the instrument is as compact as possible it is made in a simple box form, one end of the case being used to carry the crystal detector which is entirely covered in by a suitably designed lid, while the main part contains the ebonite panel and the basket inductance coil.

Case.—The complete case is shown pictorially in Fig. 54, and is made throughout of mahogany $\frac{1}{4}$ in. thick, the overall dimensions being $5\frac{5}{8}$ in. by 4 in. by



[Fig. 53a.—Photograph of Receiver shown Open.

2 in. deep, and the inside dimensions of the chamber containing the "basket" coil are $3\frac{1}{2}$ in. by $3\frac{1}{2}$ in. Holes $\frac{7}{8}$ in. in diameter and recessed $1\frac{1}{4}$ in. in diameter by $\frac{1}{16}$ in. deep are cut on each side for the main aerial and earth terminals respectively, as shown at A and E, Fig. 54. Beyond this the figure is self-explanatory.

Panel.—The panel is made of ebonite $3\frac{3}{4}$ in. by $3\frac{1}{2}$ in. by $\frac{1}{4}$ in. thick arranged as in Figs. 55 and 56. The tuning holes are made by screwing a piece of 2 B.A. rod into the ebonite until the end is just projecting from the other side; the rod is then sawn off almost flush with the panel and roughly filed flat. This operation is repeated for the forty-two plugs and then all are finally filed flush with the panel face, finishing off with medium emery cloth and oil.

Mark the centres of the plugs with a centre punch and then drill each one $\frac{1}{8}$ in. in diameter by $\frac{7}{32}$ in. deep and slightly round off the edges of the holes.

Telephone terminals are fitted in the positions indicated, as also are another pair connected by a bridge of brass strip so that on removing the bridge a loading coil for longer wave-lengths can be fitted.

The slots shown in Fig. 56 are filed in the ebonite, so that the plug leads for aerial and earth can be brought outwards when the instrument is in use, and can be folded downwards and tucked inside the cover containing the detector when the instrument is not required.

Detector.—This is built up entirely of old pieces, the ball being a brass one (from an old bedstead) and plugged and drilled for the wire holder. A simple

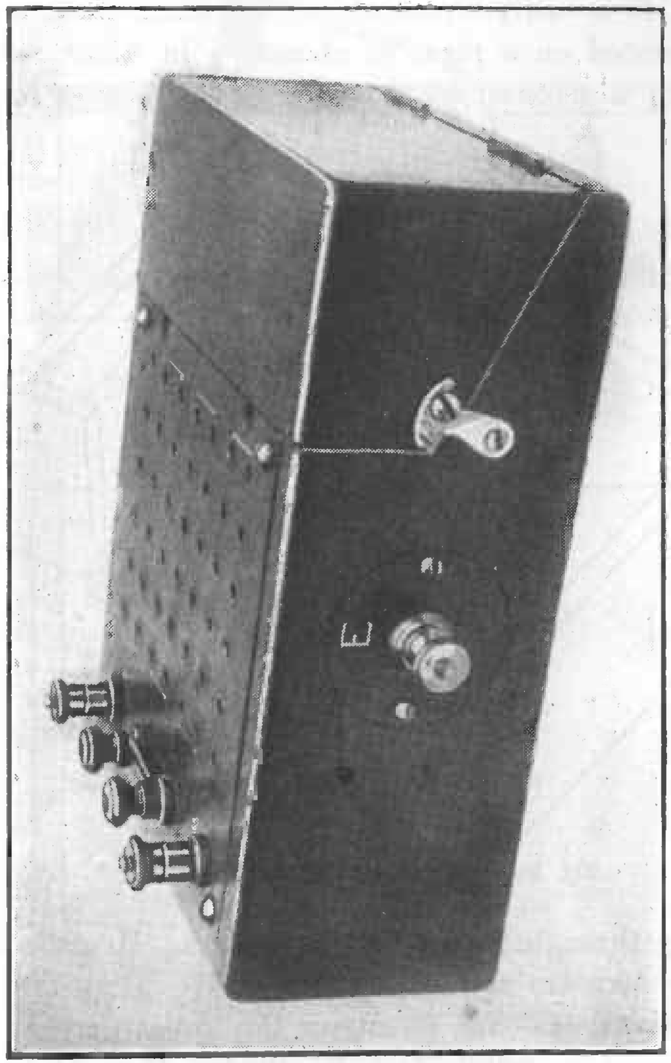


Fig. 53b.—Photograph of Receiver shown Closed.

method of holding the wire is to screw the end of the rod and then clamp the " whisker " between two nuts. It is easily replaceable. The complete detector is mounted on a piece of ebonite $\frac{1}{8}$ in. thick, which in turn is screwed to the base by four brass screws passing through four celluloid washers. Hertzite and copper wire are used as a detector.

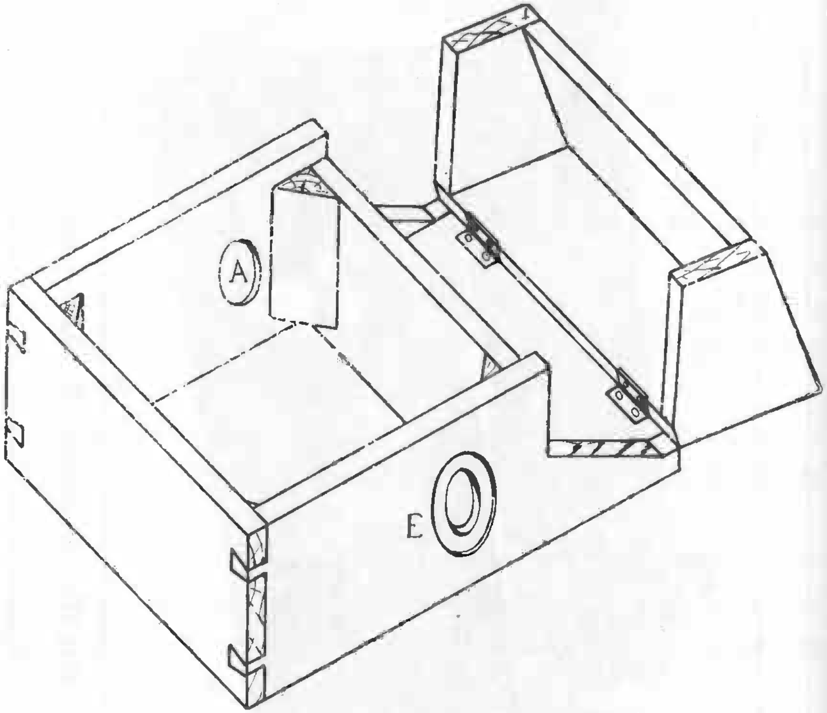

Fig. 54.—Details of Containing Case.

Inductance.—Fig. 60 shows the appearance of the former cut in celluloid $\frac{1}{16}$ in. thick. It is $3\frac{1}{2}$ in. in diameter and contains 9 vanes, the bottom of which is on the circumference of a circle $\frac{3}{4}$ in. in diameter. Seventy-two turns of No. 26 d.s.c. wire are wound on

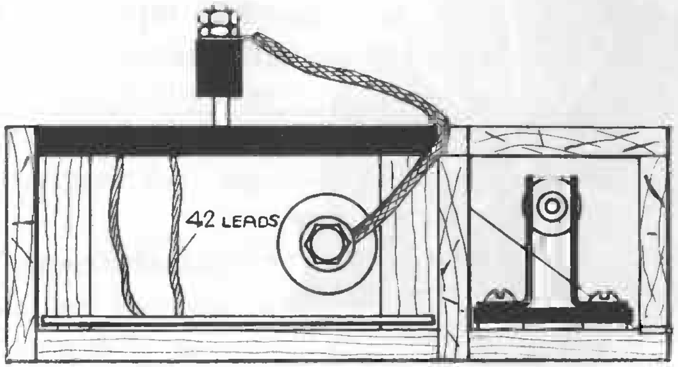

Fig. 55

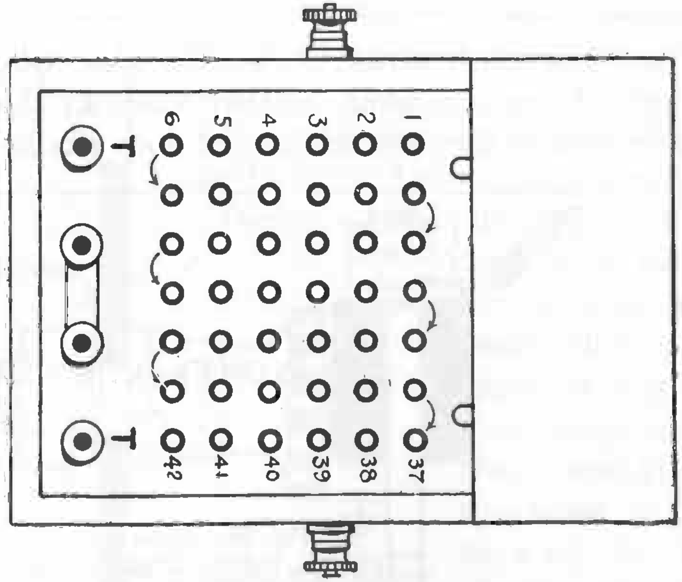

Fig. 56

Figs. 55 and 56.—Section and Plan of Receiver with Plug-in Basket Coils.

and tappings taken off in the following manner:—Starting from the inside, the first tapping is taken after the first turn, the second is taken at the next

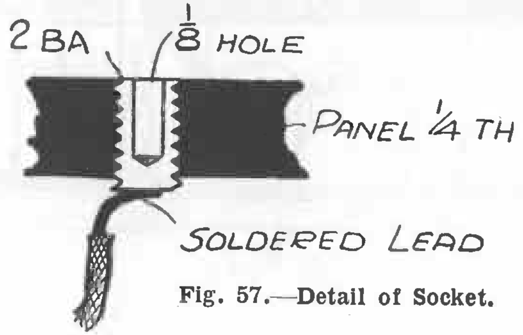

Fig. 57.—Detail of Socket.

one and one-ninth turns, i.e. on the vane following the end of one revolution, so that when all the tappings are made they are not heaped upon one another

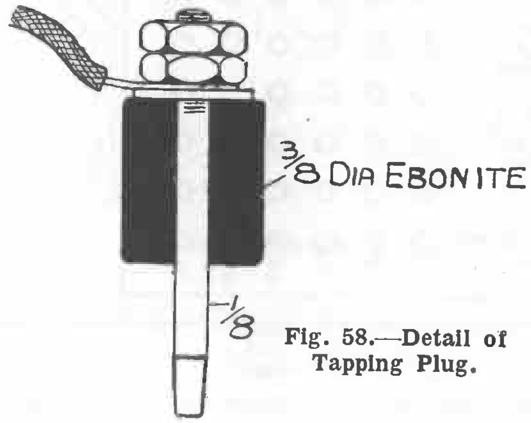

Fig. 58.—Detail of Tapping Plug.

on the same vane. The third tapping is taken after the next one and one-ninth turns, and so on. When completed, 33 tappings should be taken as just

described and 9 tappings taken at every four and one-ninth turns. The latter are for coarse tuning, and the former for fine tuning.

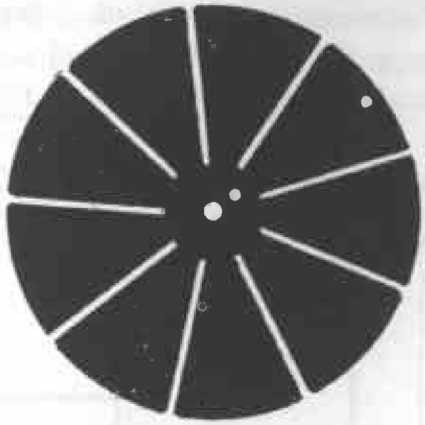

Fig. 60.—Tuning-coil Former.

Connections.—For inductance coil use a five-stranded flexible wire (called "baby" flex) and make each 5 in. long. Solder all connections, and on completion soak the whole in paraffin wax.

The plug numbers in Fig. 56 indicate the order of attaching connections.

Tuning.—As an illustration of the method of tuning, for example, it is found that 2LO comes in very well when plugs are in Nos. 2 and 41, and also when in Nos. 29 and 42, but there is a very slight difference in the result, as the difference between the length of wire

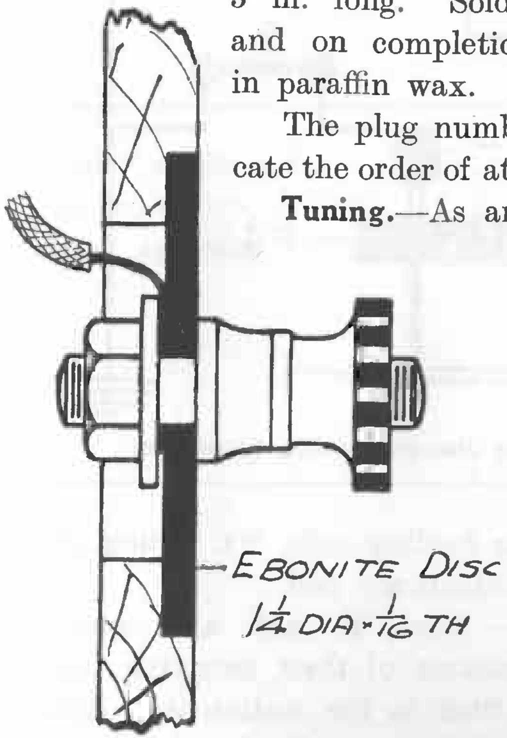

Fig. 59.—Method of Fixing Terminals.

between each pair of holes is very small. In this case the final tuning is obtained by moving the aerial and earth plugs together into either pair of holes.

Explanatory details are shown in Figs. 54 to 60 and a wiring diagram in Fig. 61, in which figure B represents bridge for loading coils, P L tuning plugs, P A panel, and I inductance coil.

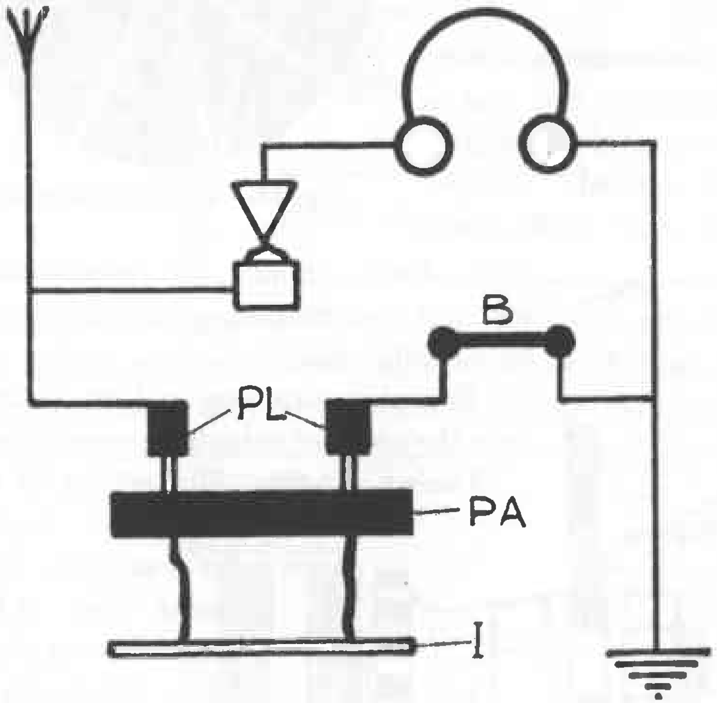

Fig. 61.—Circuit Diagram showing Connections.

Tuning Cards.—Most, if not all, amateurs memorise the calibrations of their receiving sets or have to tune each time to the station it is desired to hear. It may not be generally known that the use of a tuning card would be of great assistance. These are used in just the same way as a business man uses a file index. An example of such a card is shown above, though, of course, this may be modified according to individual requirements.

CHAPTER VII

Combined Crystal and Valve Receiver

By P. T. BEARD

THE receiver dealt with in this chapter is not new, but its many advantages are usually unknown to the newcomer in the wireless field. It is as easy to make as a simple one-valve receiver. Briefly the receiver consists of a valve used as an amplifier of radio-frequency oscillations, in conjunction with a crystal used as a detector or rectifier.

The Tuner.—An ebonite or prepared cardboard cylinder 4 in. long by 3 in. in diameter is wound with forty turns of No. 20 d.c.c. copper wire, tapped off to a seven-point switch from the following turns: 6, 12, 18, 24, 30, 36 and 40. Between turns 12 and 13 a space of $\frac{1}{4}$ in. is left as shown in Fig. 62.

Reaction Coil.—This is a basket-wound coil of No. 26 s.c.c. copper wire wound on a cork 1 in. in diameter with thirteen pieces of cycle-wheel spoke or blanket pins spaced equally round its circumference. The wire is simply wound in and out round the spokes (Fig. 63) until the coil is just of sufficient diameter to rotate inside the inductance coil without touching. When the reaction coil is wound, leave about 6 in. of loose wire at each end for connections, and soak the coil in a bath of melted paraffin wax. When the wax is just about to set, remove the coil and allow it to

harden. Afterwards the spokes can be withdrawn and the cork taken away.

A piece of brass rod 5 in. long and $\frac{1}{8}$ in. in diameter is now passed through the inductance coil in the space left between turns 12 and 13, and the coil lashed securely to the brass rod by means of adhesive tape. A hardwood or ebonite knob is fastened to the end of the brass rod so that the reaction coil can be rotated inside the inductance coil (Fig. 64).

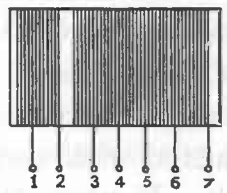

Fig. 62.—Inductance Coil.

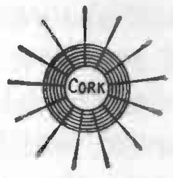

Fig. 63.—Reaction Coil.

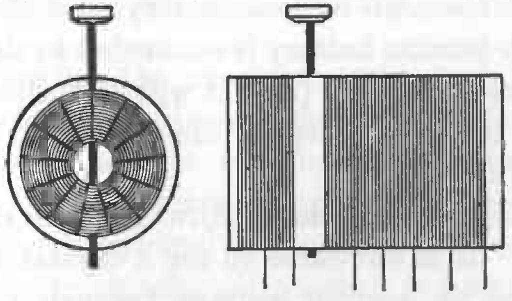

Fig. 64.—End and Side Views of Mounted Reaction Coil Fitted in Inductance Coil.

A variable condenser of about ·0005 microfarad capacity is connected between the aerial end of the inductance (A) and the handle of the seven-point switch, and the tuner is complete (Fig. 65).

The complete receiver is shown in the diagram (Fig. 65). It will be seen that the aerial is joined to the inductance coil at the end nearest to No. 1 tapping. The earth is connected to the arm of the seven-point switch, and the variable condenser is placed between the aerial and earth. The grid of the valve (G) is connected to the aerial terminal through a grid leak and condenser (C), which may be omitted with very little detriment to the signal strength. If used, the grid leak should be of two megohms resistance and the grid condenser of ·0003 microfarad capacity.

One connection of the reaction coil (which is, of course, inside the inductance coil) is connected to the plate of the valve (P), and the other connection is taken to the telephone terminal which is nearest to the positive terminal of the high-tension battery (M). Take careful note of this part of the circuit. A connection is taken from this telephone terminal to the positive of the high-tension battery, and the negative of the high-tension battery is connected to the negative of the filament battery (H). It will be noticed that the negatives of both batteries are joined to the earth terminal (E).

The Crystal Detector.—Now for the crystal detector (K). It is advisable to use a crystal which does not require an applied voltage through a potentiometer. A connection is taken from the plate of the valve (P) to one terminal of the crystal detector (K). The other terminal of the crystal is joined to the telephone terminal opposite to the one which is connected to the reaction coil. A fixed condenser (N) of

about ·01 microfarad capacity placed across the phones and high-tension battery as shown will improve results. The valve filament is supplied from a 6-volt accumulator through a variable resistance (J) of 5 ohms.

Operating the Set.—Phones of from 4,000 to 8,000 ohms total resistance should be used, or 120-ohm phones will do as well if a telephone transformer is inserted between the phones and phone terminals.

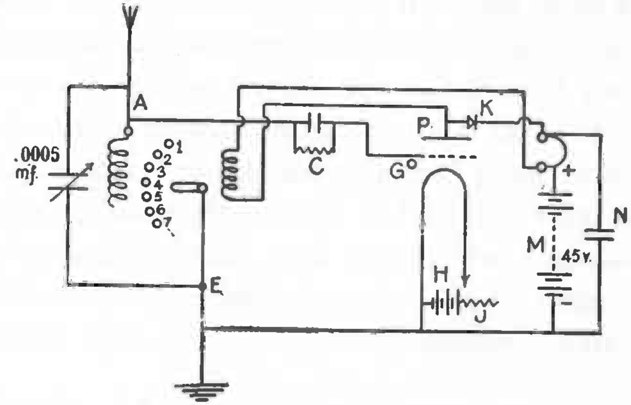

Fig. 65.—Diagram of Connections for Complete Receiver.

When testing the receiver, make sure that the crystal is correctly adjusted, then rotate the reaction coil; at the same time tap the aerial terminal with the finger. If clicks are heard in the phones each time the aerial terminal is touched, the receiver is ready to receive signals. If no click is heard, reverse the connections to the reaction coil; this will give the desired result.

With careful adjustment of the crystal the strength of signals will be from 200 per cent. to 300 per cent. louder than those obtained when using the valve alone.

Another advantage of this circuit is that by simply switching off the filament current signals can still be received on the crystal. This is an asset when the filament battery runs down in the middle of an interesting transmission.

CHAPTER VIII

Some Miniature Receiving Sets

Whilst a set carefully built on orthodox lines is a necessity for those living some distance from a broadcasting station, the simplest of sets, even those which may be classed as freaks, are capable of giving excellent results within a range of a few miles of a broadcasting centre. Some have yielded good results over a range of more than 100 miles, but this must be taken as exceptional, and not to be expected as a general rule. The sets described in this chapter are miniature sets of the simplest possible construction.

A Basket-coil Receiver

This set, as previously intimated, is limited as regards range ; that is, it can be described as a single-purpose instrument suitable for broadcast reception only.

An elevation and plan of the instrument is shown by Figs. 66 and 67.

The set consists of an ebonite block supported on four legs, between which are situated inductance coils of the " basket " type. On the top of this block is secured the crystal detector and terminals.

Constructing the Coils.—The construction of the coils is the first operation, as really the size of the base is dependent upon the outside diameter of these, but if the latter are made in accordance with Fig. 68 sufficient wire can be wound on to suit the majority of " broadcast " aerials. Disks $2\frac{3}{4}$ in. in diameter are cut from waxed cardboard, celluloid, or ebonite, and nine slots, each $\frac{3}{32}$ in. wide, cut therein, so that they reach down to the circumference of a circle 1 in. in diameter. A hole $\frac{1}{8}$ in. in diameter is drilled in the centre, and two pairs of holes about $\frac{1}{16}$ in. in diameter are made for the purpose of securing the ends of the wire.

Winding.— The wire is put on as follows: Wind on uniformly 44 turns of No. 26 d.s.c. wire on each disk and secure the ends through the holes just mentioned. It will be necessary to test these coils, the aim being to obtain perfect tuning when they are in the assembled position shown in Fig. 66.

Coupling these coils together and connecting to a crystal detector in the manner shown in the diagram (Fig. 69), it will be possible to determine the best relative position of the coils. (It must be remembered that it is important that the windings should both be in the same direction.) If, for instance, good reception is obtained with the coils 12 in. apart, then some wire must be removed from each coil, taking off one turn at a time, until with the coils about 1 in. apart good results are obtained. In the writer's case the coils each contain 38 turns, in others 36 and 44 turns have been necessary, depending on the natural wave-length of the aerial. This completed, leave 6 in. of wire projecting at each end for connecting purposes, give the

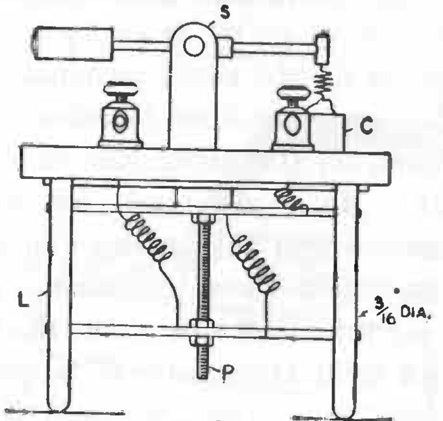

Fig. 66

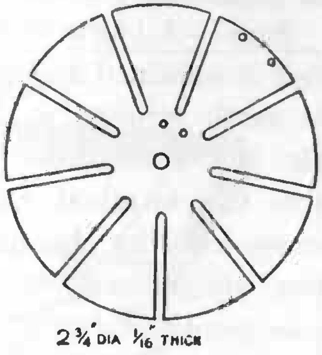

Fig. 68.—Former for Winding Coils.

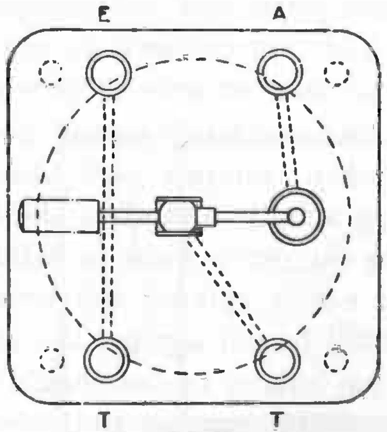

Fig. 67

Figs. 66 and 67.—Elevation and Plan of Miniature Basket-coil Receiver.

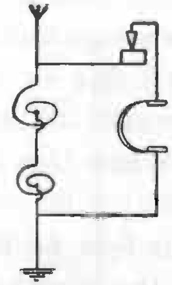

Fig. 69.—Circuit.

whole a coat of shellac varnish, and set aside until the remaining portion of the instrument is completed.

Base.—A block of ebonite $3\frac{1}{4}$ in. by $3\frac{1}{4}$ in. by $\frac{3}{8}$ in. thick is obtained and drilled for the aerial terminal A, the earth terminal E, the two telephone terminals T (Fig. 67), and counterbored on the under side to receive the terminal nuts. Holes are made for the screws securing the stirrup S and the crystal cup C, after which channels are cut underneath connecting these points as shown. On the under side of the block five holes are drilled (not right through) and tapped 4 B.A. to receive the four legs L (Fig. 66), and the centre spindle P, which is a piece of rod 2 in. long screwed 4 B.A.

Assembling.—Assemble the four terminals, crystal cup and stirrup and make permanent connections in the channels provided. The best connections are obtained by taking three or four strands of thin wire and twisting them together, as single-strand coarse wire is liable to break when clamped hard under a nut; screw in the centre spindle and then the four legs. When this is done cut out a piece of celluloid (Fig. 66) to fit over the centre spindle and between the four legs, so that it will lie flat against the under side of the ebonite base (no nuts or screws should project). Before finally assembling, connect up the inductance coils to the respective terminals, replace the celluloid and place on the first coil, taking care to insert a rubber washer $\frac{1}{2}$ in. in diameter by $\frac{3}{16}$ in. thick between. Clamp up by means of a 4 B.A. nut. Solder the wire connection between the two coils, and

twist the intervening length into a neat coil and assemble the second disk at the predetermined distance by

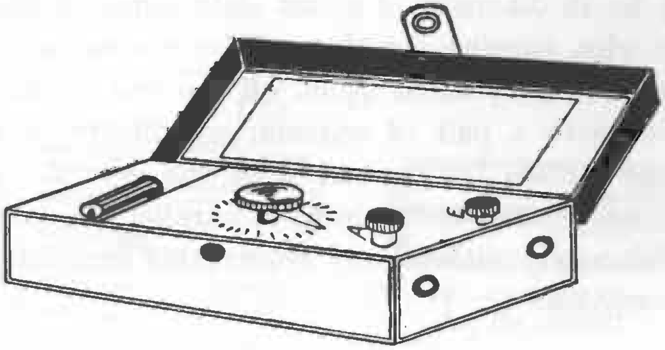

Fig. 70.—General View of Vest-pocket Receiver.

a 4 B.A. nut on each side, at the same time observing the correct direction of the coil winding.

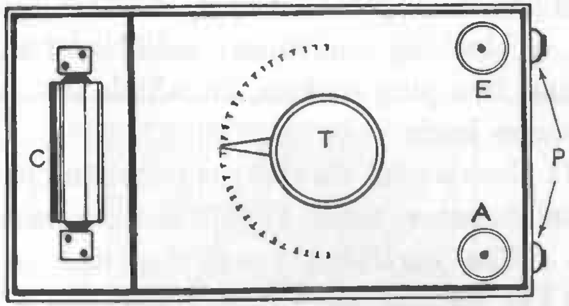

Fig. 71.—Plan of Vest-pocket Receiver.

Check over the connections carefully in accordance with the diagram Fig. 69.

The Detector.—Hertzite crystal and copper wire is probably the most satisfactory combination. The copper wire (catwhisker) is preferably made into a coil $\frac{1}{4}$ in. in diameter of about eight turns of No. 36-gauge wire, turning out the end for contact with the crystal. Cutting about $\frac{1}{32}$ in. off the end of the catwhisker with a pair of scissors periodically provides a clean surface for contact with the crystal. Four headphones (each 4,000 ohms) in parallel can be used simultaneously without any appreciable diminution of the reception.

Building a Vest-pocket Receiver

The sketch (Fig. 70) gives a general idea of the appearance of a vest-pocket receiver contained in a safety-razor case. The instrument has only one adjustment, the small tuning knob in the centre of the panel.

Elements of the Set.—Briefly, the receiver consists of a variable tuning inductance, a cartridge crystal detector, a blocking condenser, aerial and earth terminals, and two plug sockets, to which are connected the telephone leads.

Fig. 71 gives a plan view of the panel and position of the crystal detector, while Fig. 72 is a diagram of connections. The cartridge containing the crystal is shown in Fig. 73, and the tuning inductance in Fig. 74.

The Case and Panel.—The first item requiring consideration is the containing case. The ordinary safety-razor case is ideal for this purpose. An ebonite panel is now cut to fit tightly into the case, leaving a small partition in which the crystal is housed. The ebonite panel must be securely supported, either by means of a small strip fixed in the inside of the case or by means of small countersunk screws passing through the sides.

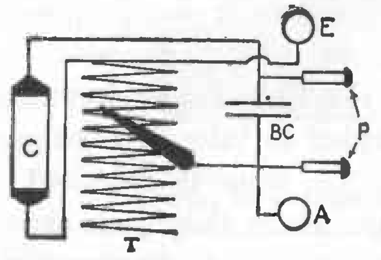

Fig. 72.—Diagram of Connections of Vest-pocket Receiver.

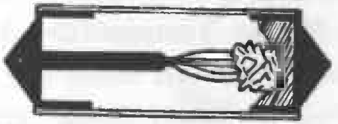

Fig. 73.—Cartridge Containing the Crystal.

The Tuning Coil.—To the under side of the ebonite panel is fitted the tuning inductance, which consists of No. 32 enamelled wire wound on an ebonite former $\frac{3}{16}$ in. thick, 2 in. deep, and as wide as can be got into the case, that is, a shade smaller than the ebonite panel itself.

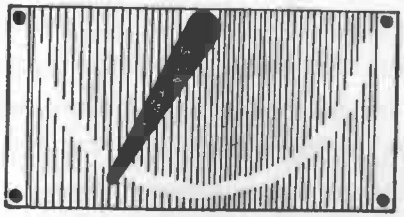

Fig. 74.—Tuning Inductance.

The Contact Finger.—A small contact finger is now made up, soldered to a short spindle, and arranged to make contact on the bared portion of the inductance winding, as shown in Fig. 74. This contact finger is moved by means of the tuning knob T on the top of the panel. A pointer may be fitted to enable comparative tests to be made, a scale being engraved on the panel, as indicated in Fig. 71. Two small terminals are fitted at one end of the panel for the purpose of connecting the aerial and earth wires to the set.

Phone Terminals.—At the end of the containing case two small holes are drilled to take two ordinary valve sockets; these must be securely mounted in position. The holes through which they pass should preferably be bushed with ebonite to increase the insulation efficiency of the set.

A pair of valve legs, corresponding to the sockets, should be soldered to the phone, which, for compactness' sake, may consist of a single 4,000-ohm receiver without a head-band.

The Detector.—The cartridge crystal detector is very simple in construction: a short length of ebonite or fibre tube is obtained and two small metal caps made to fit tightly into each end. One cap should be filled with Wood's alloy, and a good sample of a galena crystal mounted therein. The other cap is fitted with a metal rod $\frac{1}{8}$ in. in diameter, to the end of which are soldered several wires of about No. 26-gauge copper wire. Hard-drawn wire should be used on account of its springiness.

With regard to the metal end cap, these are best turned out of solid brass rod, the ends being pointed for the spring-clip holder provided. This holder may consist of two right-angled brass strips screwed to the

bottom of the containing case. It is, of course, understood that the cartridge is assembled so that the bunch of copper wires makes contact with the crystal in several different places.

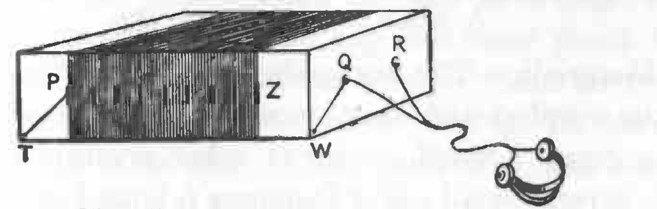

Fig. 75.—Match-box Receiver.

The Condenser.—The blocking condenser consists of eleven sheets of tinfoil, 2 in. by $1\frac{1}{2}$ in., interleaved with wax paper and mounted, underneath the panel on the bottom of the case.

Connections.—The diagram of connections is given in Fig. 72. The telephones are connected to the plug sockets P, the aerial and earth to A and E, B C

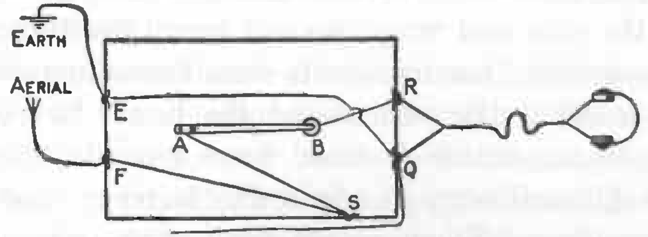

Fig. 76.—Diagram of Connections of Match-box Receiver.

being the blocking condenser, T the tuner, and C the crystal.

Range of Set.—Using an aerial of the regulation length and height the broadcast concerts should come through very clearly, while a certain amount of Morse and amateurs' transmissions may be picked up under good conditions.

Quite sharp tuning can be obtained with the wiring as given in Fig. 72.

A Match-box Receiver

Materials.—The materials required for this set are of the simplest and merely comprise : 1½ oz. of No. 26 d.c.c. wire, 1 small galena or other crystal, 1 match-box, several small paper fasteners (about ¼ in.), 4 large paper fasteners (about ½ in.), a small strip of thin brass, and the screw cap of a metal-polish tin.

Winding the Tuner.—The amount of wire, etc., depends on the size of the match-box used ; the best is one of the largest. At each end of the box make two holes about 1 in. apart, and through these holes put the large fasteners. About a ¼ in. from the end on one side of the box put a small fastener P (Fig. 75), with the head inwards and through the cover only. Take the wire and wrap the end round the fastener P on the outside, leaving about 6 in. for wiring. Then begin to wind the wire round the box. Every five turns put in another fastener, head inwards, bare the wire a bit and wrap it round the fastener, and continue winding. When within ¼ in. of the end put in another fastener, cut the wire, bare the end and wrap it round the last fastener.

Through the inner box part put a fastener S, as shown in Fig. 76, so that its head will touch the head of the fastener Z when the box is closed.

The Detector.—The detector is easily made with

the piece of galena, the strip of brass, and the screw-cap. Take the screw-cap and cut four slits in the side to about half-way down as in Fig. 77. Bore a hole in the bottom of the cap and fasten it down to the inside part of the box with a small fastener as B (Fig. 76). Then put the crystal in the cap and bend down the edges, thus holding the crystal firmly. Take the strip of brass and cut it into the shape of Fig. 78, boring a hole in the wide end. Then bend it to the shape shown in Fig. 79, and fasten it with a fastener at the proper distance from the cup.

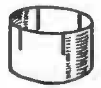

Fig. 77.—Crystal Cup.

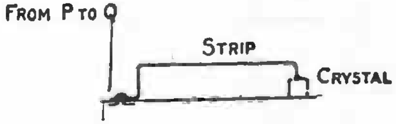

Fig. 79.—Detector.

Fig. 78.—Detail of Detector.

Wiring Connections.—Having completed the tuning coil and the detector the next thing is the wiring. Through the outer cover in the bottom corner bore a small hole T (Fig. 75), and through it thread the wire from P. Run wire along the inside of the outer cover so that it comes out at W at the other end, then join it to Q. Next attach a wire to the cup B and connect it to R on the inside. Then attach a wire to the strip A and connect that wire to the fastener S ; connect the fastener S to the fastener F, and attach a wire to Q on the inside and join it to E.

If desired, a small knob can be glued on to the box between E and F for the purpose of tuning.

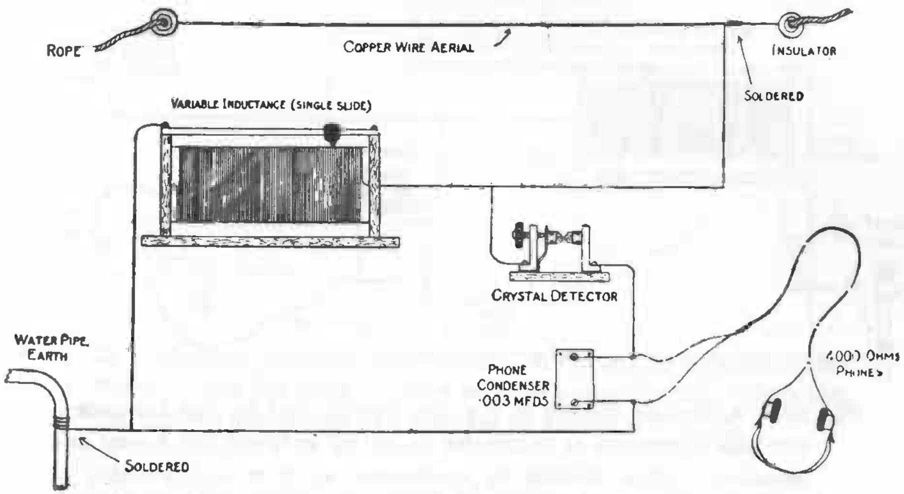
The head-phones are attached to the terminals R and Q, the aerial is attached to F and the earth to E.

Operation.—In use the point of the strip A should be moved about until signals are heard. Tuning is then effected by pulling the inner part of the box out.

CHAPTER IX

Crystal Circuits

THE illustrations (Figs. 80 to 85) in this chapter show diagrammatically (as distinct from conventionally) the common circuits used in crystal sets.



Rope

Phone Condenser ·003 MFDS
4000 Ohms Phones
Soldered

Fig. 80.—**Diagram showing the Method of Connecting up a Single-slider Tuning Inductance to a Crystal Detector. This manner of Coupling is termed "Direct-coupling."**

There are various types of tuning devices in general use, the more common, perhaps, being the single-layer solenoid type. These may be divided up into two classes—the "tapped" and the sliding contact tuners. Dealing with the single coil direct-coupled tuners, the most effective as regards fine tuning is doubtless the single slider tuning coil as illustrated in Fig. 80. Here it will be seen that tuning is effected by simply sliding a spring contact along the coil. It is possible to obtain fairly accurate tuning to within one complete turn of wire on the coil. For finer tuning a variable condenser is often inserted in the aerial system, in series with the tuning coil as in Fig. 81. This condenser certainly facilitates short-wave tuning, but is often undesirable owing to its effect in causing unbalanced tuning. Another type of sliding contact tuner is the two-slider. The original object of a two-slider coil was to form an auto-transformer coupling which would give a reasonable transformer step-up in signal strength without the usual losses attendant to the use of a loose-coupled air-core transformer. The wiring of this two slider is shown by Fig. 82. Here it will be seen that the one coil governs two circuits—the aerial, one portion of the coil and earth being one circuit, and the crystal, phones, one section of the coil and earth, the other circuit. The aerial to earth circuit is the primary, and the crystal, coil, and telephone circuit forms the secondary. Fairly correct tuning is obtained from the primary circuit, but when the secondary circuit is adjusted with a greater number of turns of wire to obtain the necessary transformer step-up, the secondary circuit becomes out of "tune." To obviate this, a variable condenser is inserted in parallel across the secondary section of the coil as in Fig. 83. By means of this condenser, accurate

secondary tuning is possible, allowing scope at the same time for any reasonable transformation ratio of turns between the primary and secondary sections of the tuning coil. Provided accurate tuning is employed, this type of tuner is probably the most desirable from the point of view of the crystal user.

Another method of tuning is that known as "tapping" the coil. Fig. 84 illustrates the single switch-arm type. Correct tuning, however, is not possible unless the tappings are accurately taken at calibrated points for certain wavelengths. A tuning condenser may, however, be connected between the aerial and earth terminals of the coil to facilitate accurate tuning. A more efficient type of tapped coil is that shown by Fig. 85 where two switch-arms are employed. One

switch-arm is designed to make contact over a portion of the coil which is tapped in units of turns, the other switch-arm making contact over the remainder of the coil which is tapped in sections each equalling the total number of turns covered by the unit switch-arm. Suitably designed, and for short wavelengths, it is possible with this type of tuner to obtain correct

tuning to within one turn of wire on the coil. This type of tuner has one great advantage over the slider method, inasmuch as the wire on the coil is not worn away or cut through by constant use of a slider. These fine particles of copper, worn from the coil by the slider, tend to bridge neighbouring turns of wire on the slider coil. In the tapped coil this trouble is eliminated, but the advantage is lost if the tapping studs are poorly insulated. On each diagram will be seen the necessary crystal detector for detecting and rectifying the signals, and also the telephone condenser and the telephones. The telephone condenser is not absolutely an essential instrument, as the self-capacity of the telephone windings and the telephone leads is often adequate. However, it will generally be found that a fixed condenser of capacity between ·001 and ·005 microfarads will considerably improve the note of the signal heard in the telephones. All bare wire connections should be thoroughly clean and soldered, all terminal connections should be clean and tightly bolted. Do not grind or break crystal surfaces unnecessarily and periodically wash the surface of the crystal with methylated spirits by means of a small brush.

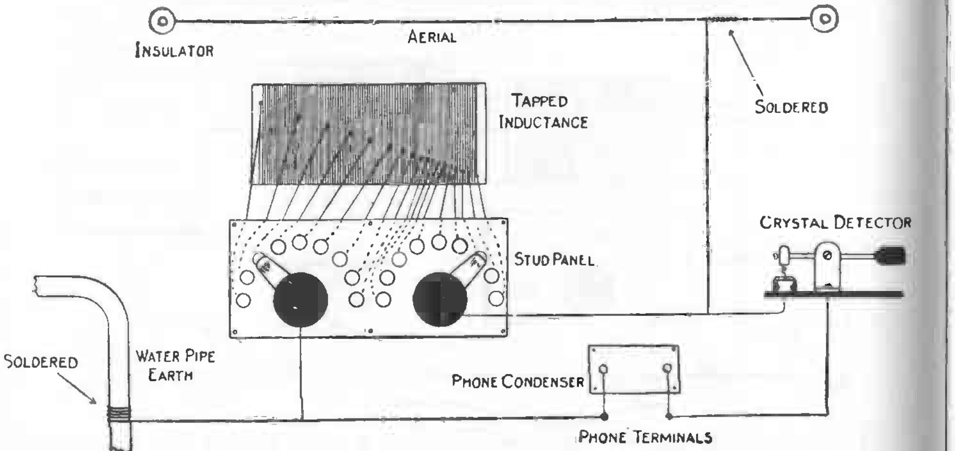

Fig. 85.—An Effective Means of Wiring-up a Tapped Coil to Two Switch-arms which Facilitates Fine Tuning.

CHAPTER X

How Crystals Work

What the Crystal Does.—Wireless signals are transmitted in the form of waves created in the ether, which, striking the receiver aerial, cause small alternating currents to travel up and down it. As these currents are of a very high frequency, the ordinary wireless telephone receiver cannot detect them. It is necessary, therefore, to rectify them, or, in other words, change them into unidirectional currents, before passing them through the telephones. The rectified currents produce a movement of the telephone diaphragms and thus the signals are made audible.

Certain kinds of crystals, such as carborundum, zincite, bornite, silicon, galena, molybdenite and iron pyrites (see Figs. 86 to 93, which show crystals enlarged to about three times normal size), have the peculiar property of being able to rectify small alternating currents. An explanation is given to show how they do this.

How a Crystal Rectifies.—A crystal rectifies because it allows current to flow through it in one direction and does not, to any appreciable extent, allow current to flow through it in the opposite direction. It is practically a uni-directional conductor. The ratio of currents flowing in opposite directions through

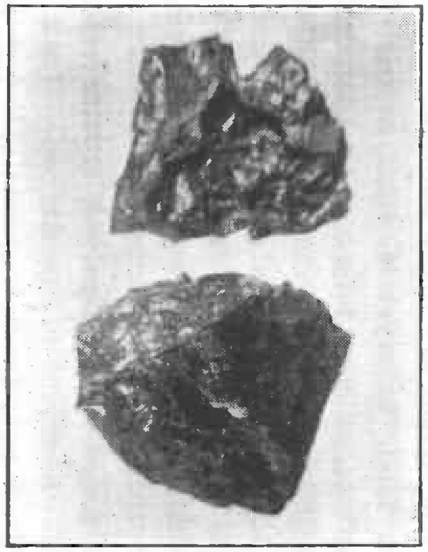

Fig. 86.—Silicon.

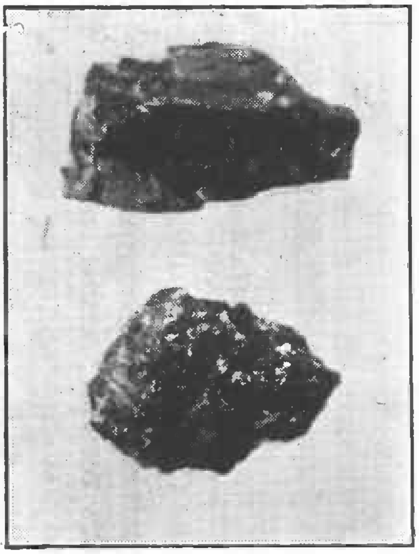

Fig. 87.—Galena and Special Galena.

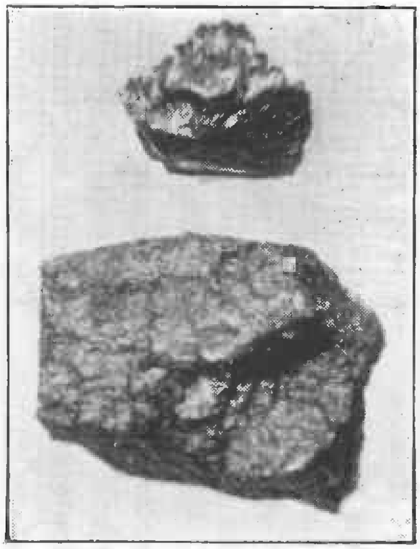

Fig. 88.—Bornite.

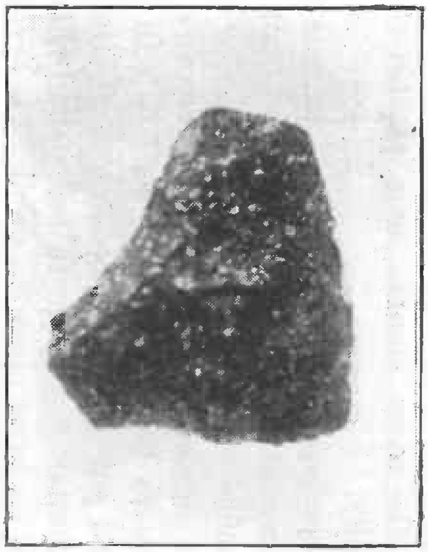

Fig. 89.—Radiocite.

a good crystal should be about 40 : 1. It will be understood that the crystal acts electrically, very much in the same manner as a ratchet-wheel acts mechanically.

Carborundum Crystals.—Carborundum is probably the best crystal for all-round use. It is not affected by mechanical vibration nor by fairly heavy electrical discharges across it, and it is very sensitive. This crystal has to be used in conjunction with a 4-volt battery and potentiometer, because it requires a small initial potential or voltage to be applied across it to bring it to its most sensitive point. Carborundum is used with a flat steel surface, the rectification taking place at the point of contact. This crystal is manufactured by fusing carbon and silicon together in an electric furnace. In practice three kinds of carborundum crystal are met with : (*a*) a hard dark variety, having great metallic lustre which has poor rectifying properties ; (*b*) a soft crystal of a pale-green colour, a colour due to the presence of copper and iron salts (this type of crystal is a very poor rectifier) ; (*c*) a dark grey crystal which will be found to give the best results as regards sensitivity and stability of action.

The Perikon Detector.—The most popular crystal detector is without doubt the perikon detector. This is a combination of either zincite and bornite or else zincite and tellurium. The latter combination is usually found to give the better results. Zincite, a zinc-oxide ore, is dark red in colour ; bornite is a compound of copper and iron sulphides, being bluish grey

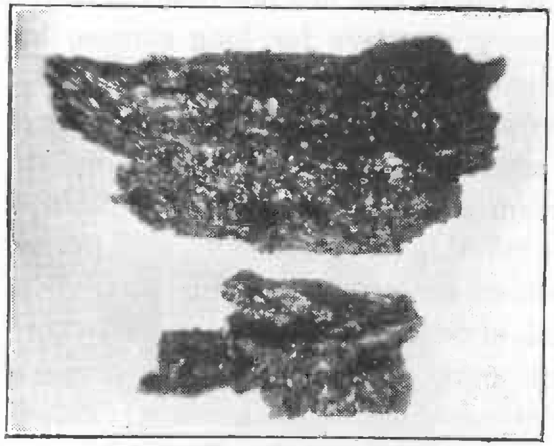

Fig. 90.—Carborundum.

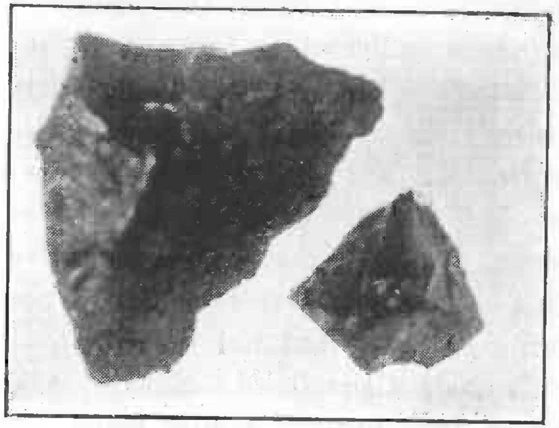

Fig. 91.—Copper Pyrites.

in appearance and fairly heavy. Tellurium is a light-coloured metal. The perikon detector does not require a potentiometer because the voltage of the incoming signal is sufficient to bring it to its sensitive point. It has the advantage of being fairly easy to adjust. Also when a crystal becomes slightly insensitive it can be scratched with a knife and a new surface used. To obtain the best results it is usually found that the crystals must make a light contact with each other. This detector is more sensitive in action than the carborundum type, but not so robust.

Other Crystals Considered.—Silicon, galena, molybdenite and iron pyrites, whilst being serviceable for experimental work, do not give such satisfactory general results as either carborundum or the perikon detector. All these crystals are minerals. Silicon is light grey in colour and has not many sensitive points. Galena is very sensitive for long ranges, but strong signals destroy its sensitivity. It is bluish black in colour, has a metallic lustre, and is heavy. When using this crystal it is usual to have a graphite contact in conjunction with it. Molybdenite is dark in appearance and is suitable for the reception of strong signals; it is convenient for use in portable sets. Iron pyrites is a cubical crystal, being very metallic and heavy. It possesses many of the properties of carborundum but is not so sensitive.

Finding the Best Crystal.—The only sure way to obtain a good crystal is to search for sensitive points amongst several specimens. It is wise to remember that sensitivity is not everything; a good crystal

Fig. 92.—Permanite.

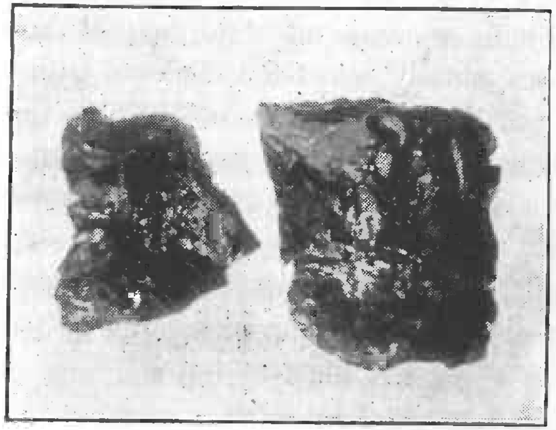

Fig. 93.— Zincite.

should have the qualities of being constant in action and of not being affected by atmospheric disturbances. Such crystals as " radiocite " and " permanite " are usually sensitised forms of galena. They are very sensitive but not constant ; a fine copper wire contact is used in conjunction with them.

There is plenty of instruction and amusement to be had with a good crystal set. The range of a crystal set is about 300 miles for ordinary ship stations and 20 or 30 miles for high-power telephony.

CHAPTER XI

Making a Buzzer

By A. W. HULBERT

THIS chapter deals with a new type of buzzer, one which utilises a circular armature or diaphragm instead of the usual flat strip of metal. Due to the fact that this diaphragm is supported all round, it is possible to have the magnet almost touching the diaphragm, resulting in a more sensitive instrument and one capable of producing an extremely high-pitched note.

The overall dimensions of the instrument are also considerably less than the standard instrument, and having a minimum of working parts it is very easy to make.

Constructional Details.—Fig. 94 is a section of the instrument. A circular ebonite case B, with a snap-on lid, is fitted with an electro-magnet M, which is wound on a strip of soft iron P which serves the double purpose of a core for the magnet and also a support. The soft iron strip P is bent round and mounted on the bottom of the ebonite case with the aid of two screws, the opposite arm to that carrying the coil M being in contact with the diaphragm D, which rests on a ledge turned in the ebonite case. The distance between the diaphragm and the pole of the magnet M is approximately $\frac{1}{32}$ in.

The lid of the ebonite case B is undercut to enable the diaphragm to vibrate. Mounted on the top is a contact screw S and a terminal F. The other terminal (not shown in Fig. 94) is connected to one end of the magnet winding, the other end being earthed to the polepiece P. The passage of the current through the instrument is therefore from the battery or accumulator to the terminal F, and the metal plate to the contact screw S, across the contacts and the diaphragm D to the pole-piece P, and through the magnet winding to the terminal T (Fig. 95), and thence back to the battery.

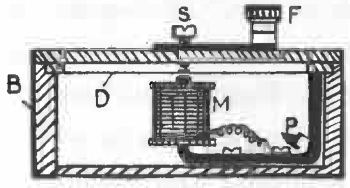

Fig. 94

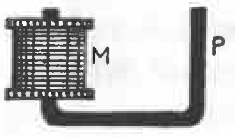

Fig. 96

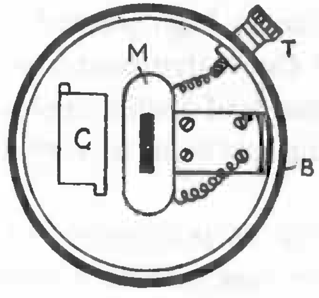

Fig. 95

Fig. 94.—Section of Complete Buzzer.

Fig. 95.—Details of Interior showing Connections.

Fig. 96.—Pole-piece and Coil.

Due to the fact that the snap-on lid clamps the diaphragm securely all round, it is possible, as mentioned previously, to have the diaphragm very close to the magnet, thereby producing a high-pitched note.

The Magnet.—With regard to the construction of the magnet M, this is wound on a metal former made up by soldering two metal cheeks to one arm of the metal strip P. This strip should measure $\frac{5}{8}$ in. wide by $1\frac{1}{2}$ in. long, and may be cut from sheet-iron $\frac{1}{2}$ in. thick. This is bent up as shown in Fig. 96; that portion forming the core of the magnet should be insulated by means of waxed silk, which should also be gummed on to the inside of the cheeks. The magnet is wound with No. 36 d.s.c. wire, the last layer but one being covered with a strip of varnished silk. The final layer of wire should be wound on very carefully and secured by looping the last turn under itself, the complete coil then being soaked in melted paraffin wax.

The Pole-pieces.—The complete coil and iron core P should now be placed on a surface plate or other flat base and the heights of the two pole-pieces carefully measured. The arm or pole-piece on which the coil is wound must be $\frac{1}{32}$ in. shorter than the other. The height of the other pole-piece must be such that it just reaches a shade higher than the ledge in the ebonite case B, so that when the metal diaphragm D is in position direct contact is made with the pole-piece P.

The Diaphragm.—The diaphragm D may be one taken from an old telephone receiver, the only addition being a contact stud soldered in the centre. Both this and the contact on the screw S should be of german-silver or other suitable alloy. The actual sparking may be considerably reduced by fitting a small condenser C (Fig. 95) in the case and connecting this across the contacts.

The Case.—The ebonite case B can easily be turned up by anyone possessing a lathe, or one may be purchased from an electrical dealer. The battery voltage may be anything from 2 to 4 volts, and when the buzzer is used exclusively for testing faults in the circuits the terminals may be dispensed with and a length of twin flexible lead soldered on permanently.

CHAPTER XII

Receiving C.W. Signals on a Crystal Set

By E. H. ROBINSON

It is frequently stated that a simple crystal receiving set will enable the listener only to pick up spark stations and telephony, and that valves will have to be installed before continuous-wave (C.W.) signals can be satisfactorily received. This is true to a certain extent, but this chapter shows how some of the louder C.W. stations can be received by means of a very simple addition.

C.W. Signals.—The reason why C.W. signals cannot be heard on ordinary crystal circuits is that when the key at the transmitting station is pressed down a continuous rectified current passes through the head telephones of the receiver, not an interrupted one as in the case of spark and telephony, with the result that no sound is heard except perhaps a faint click when the key is depressed or raised. If, however, an interrupting device, capable of making and breaking the circuit at a high rate, say 500 times a second, is inserted between the crystal and the phones, then any continuous current in the phones will be broken up into a musical note which is clearly audible.
